Mr. Shaw also testified that in his opinion the 2013 shapefile currently represents the best available information for determining TFCC's actual irrigated acreage. Hr'g Tr. vol. IV, at 164–65. Finally, the Director has letters from TFCC's counsel stating that from 2014–2022 the number of acres TFCC irrigated has not varied by more than 5% from the previous (2013) shapefile numbers. Ex. 337.

The Ground Water Users also contend that "Jennifer Sukow testified that [the 2017 lands] data set[] represent[s] the best science available to determine actual irrigated acreage . . . ." IGWA's Post-Hr'g Br. at 14. The ground water users are mistaken. During the hearing, Ms. Sukow testified that the 2017 irrigated lands data set was the best data for *model calibration*. Hr'g Tr. vol. I, at 69. Model calibration employs hindcasts, not forecasts. As noted above, the

2017 shapefile was created to assist Department staff in determining historic irrigation demand within the ESPAM boundary during 2017 for use in model calibration. *Id.* at 68, 140–41.

At the hearing and in their post-hearing briefing, the ground water users state that the burden is on TFCC or the Department to create a new shapefile that identifies the number of acres TFCC can irrigate in 2023. The ground water users are mistaken. To reduce TFCC's predicted irrigated acreage below 194,732 acres, the burden is on the junior ground water users to establish the accuracy of a lesser number (e.g., 180,956) by clear and convincing evidence. "Once a decree is presented to an administrating agency or court, all changes to that decree, permanent or temporary, must be supported by clear and convincing evidence." *A & B Irr. Dist.*, 153 Idaho at 524, 284 P.3d at 249. The ground water users did not establish an alternative number of acres irrigated by clear and convincing evidence. In short, the ground water users failed to satisfy their burden of proof.

5. Supplemental acres

When determining the total acreage irrigated with surface water by SWC entities, the Department may consider supplemental ground water use. *Fifth Methodology Order* ¶ 23, at 10, ¶ 1, at 40. If acreage is irrigated with ground water instead of surface water, less surface water is needed for irrigation, and any surface water demand shortfall should decrease. In the Fifth Methodology Order, the Department determined that it was without sufficient information to determine the extent of supplemental irrigation on lands within the service areas of the SWC entities. *See Id.* Without sufficient information on supplemental ground water use, the Director is prohibited from reducing a water user's full decreed entitlement. *2014 District Court Order*, at 19 (Holding that the Director was prohibited from administering less than the seniors full decree given that "the record d[id] not contain evidence that acres accounted for . . . [we]re being irrigated from a supplemental ground water source . . . ."). The record in this matter equally lacks sufficient evidence to justify a reduction of the total number of acres irrigated with surface water by SWC members.

IGWA argues that at least some TFCC members have supplemental rights. IGWA's Post-Hr'g Br., at 15. The Department agrees that TFCC's manager and expert Chuck Brockway testified that some TFCC members have supplemental water rights, but he also opined the number is very low. Hr'g Tr. vol. IV, at 52–53.

In his 2014 District Court Order, Judge Wildman noted that:

> [T]he parties fail to cite the Court anything submitted before the Department in either written form or via oral testimony establishing the use of supplemental ground water by individual irrigators within the Coalition.

2014 District Court Order at 19.

The Ground Water Users bear the burden of proving by clear and convincing evidence that SWC acreage was irrigated with supplemental ground water. The Ground Water Users failed to proffer sufficient evidence concerning the quantity of acres TFCC members could

irrigate with supplemental ground water rights. Assertions that IDWR records should identify overlapping ground water rights or that ground water pumping information is best known by the SWC does not change the standard of proof and does not shift the burden of proof borne by the ground water users.

6. The Department's adjustments for "wheeled water"

At times canal companies transport water for third parties through their respective water delivery systems. This transported water, which does not go to meet the canal company member's water supply, is often called "wheeled water." When calculating reasonable in-season demand, it is important to remove wheeled water from SWC diversions. For example, suppose the SWC diverted 3,500,000 acre-feet on a particular year, but 200,000 of those acre-feet was wheeled water. It is necessary to remove the 200,000 acre-feet of wheeled water when calculating SWC's demand, lest it appear SWC members were diverting and using 3,500,000 acre-feet, rather than 3,300,000.

IGWA's expert Sophia Sigstedt advised that her calculations revealed, in determining SWC's 2018 diversion, that IDWR failed to account for approximately 5,000 acre-feet of water wheeled by AFRD2. Ex. 837A, at 20. According to Ms. Sigstedt, IDWR failed to properly subtract all AFRD2's wheeled water in 2018, resulting in a diversion that was 5,000 ac. ft. too high. *Id.* at 16.

On rebuttal, Matt Anders testified that AFRD2's diversion was inaccurately calculated, and the inaccuracy resulted in AFRD2's diversion being 5,000 ac. ft. *too low*. Hr'g Tr. vol. IV, at 173–74. In other words, the miscalculation benefited the Groundwater Users and harmed the SWC, not the other way around.

In sum, there is no evidence that storage water wheeled by the SWC was incorrectly added to the SWC's 2018 surface water demand.

7. 5/8 inch per acre vs. 3/4 inch per acre

At hearing and in its summary brief, IGWA argues that "TFCC shareholders can raise crops on 5/8 inch per acre [headgate delivery] without suffering material injury." IGWA Post Hearing Brief, at 7, 9, 10. However, TFCC's seasonal headgate delivery rate is not the basis for evaluating injury in the current methodology. As IGWA acknowledges, "the Methodology Order does not actually utilize a 3/4-inch headgate delivery, 5/8-inch headgate delivery, or any other headgate delivery as part of its material injury determination for TFCC." *Id.* at 8.

Rather, as IGWA correctly states, the Methodology predicts injury using a baseline year. The baseline year is selected by analyzing climate, available water supply, and current irrigation practices from a single year or average of years. *Fifth Methodology Order* ¶ 8, at 3. The Idaho Supreme Court has affirmed that data from a baseline year can be used to determine reasonable in-season demand and predict material injury. *In re Distribution of Water to Various Water Rights Held by or for the Ben. of A&B Irr. Dist.*, 155 Idaho at 653, 315 P.3d at 841.

Undaunted, IGWA compares baseline year injury determinations to historical TFCC seasonal headgate delivery rates and concludes, "a hindcast of the Fifth Methodology Order applying it to the time period 2000-2022 shows it generating DS predictions . . ., even though TFCC rarely suffers injury in reality." IGWA's Post-Hr'g Br. at 11–12. IGWA presumably determined there was no "injury in reality" because the Methodology predicted a demand shortfall in years when TFCC received a seasonal or partial season 3/4-inch headgate delivery. IGWA's argument is unpersuasive because, by its own admission, it is relying on a determination of injury that is not a component of this or past methodologies.

C. Efficiency & Waste

CM Rule 42.01.d and g advise that two of the factors the Director may consider in determining whether senior irrigation water right holders are using water efficiently and without waste, while still suffering material injury, are:

> d. [T]he rate of diversion compared to the acreage of land served, the annual volume of water diverted, the system diversion and conveyance efficiency, and the method of irrigation water application[;] [and]
>
> . . . .
>
> g. The extent to which the requirements of the holder of a senior-priority water right could be met with the user's existing facilities and water supplies by employing reasonable diversion and conveyance efficiency and conservation practice . . . .

In substance, 42.01.d and g authorize the Director to consider whether senior appropriators are wasting water via various unreasonable or inefficient practices.

Project efficiency for each surface water delivery system is unique, depending on numerous factors, including but not limited to: (1) length of delivery system; (2) geological materials through which the system delivers water; (3) nature of structures that deliver water; and (4) method of application of irrigation water. *Fifth Methodology Order* ¶¶ 29–30, at 12–13. In the *Fifth Methodology Order*, the Director calculated recent historical project efficiency (as compared to general "project efficiency") for each SWC member for the 15-year period from 2008 through 2022. *Fifth Methodology Order* ¶ 32, at 14.

The crop water need ("CWN") for each SWC entity for the upcoming season is calculated by averaging each entity's crop mix for the previous three previous years. Off. Noticed Doc. NRT METRIC_SWC_TWG_11-17-22, at 6.[9] Averaging crop mix for the preceding three years is necessary to reflect possible changes in irrigation demands caused by variability in annual crop mix. The SWC's projected reasonable in-season demand ("RISD") for the upcoming season is calculated by dividing each entity's CWN by its recent historical project efficiency.

[9] Available for download at https://idwr.idaho.gov/legal-actions/delivery-call-actions/SWC/, "Materials Department Witnesses May Rely Upon at Hearing—May 5, 2023". Downloaded folder pathway: 2022 Technical Working Group (TWG)\Meeting 11-17-22 Forecast Supply & NRT METRIC\NRT METRIC_SWC_TWG_11-17-22.

The Ground Water Users contend the Director's efficiency analysis is inadequate because it fails to adjust for on-the-ground efficiency projects, e.g., canal lining. IGWA's Post-Hr'g Br., at 15. The Ground Water Users argue the Director should require the SWC to satisfy a higher efficiency standard than the recent historical project efficiencies.

The Ground Water Users also criticize the calculation of recent project efficiencies as being circular. Cities' Closing Br., at 7; *see also* IGWA's Post-Hr'g Br., at 15. In effect, the ground water users argue that if the SWC's irrigated acreage number is reduced, but the amount of water delivered doesn't change, the only result will be a reduced efficiency value. IGWA's Post-Hr'g Br., at 15. While the mathematical argument is correct, the purpose of the argument is unclear. It appears the purpose may be to establish that the calculated efficiency numbers are valueless.

To remedy the perceived efficiency calculation errors, the Ground Water Users contend the Department should jettison its historical efficiency analysis and instead judge SWC members efficiencies by comparing them to industry standards. Cities' Closing Br., at 7. The Director disagrees.

The Cities' expert, Greg Sullivan, conceded that the Court has previously rejected the industry standard approach for which the ground water users currently advocate. Hr'g Tr. vol. II, at 201. The Court has already determined that the methodology order's approach to calculating the efficiencies of SWC members is acceptable. *2014 District Court Order*, at 30–31. Mr. Sullivan further admitted that there were no per acre industry standard diversion rates for large open canal systems—as each entity would be different—and that he used the term "industry standard" to mean reasonableness of TFCC's operation compared to its irrigation efficiencies. Hr'g Tr., vol. II, at 225, 237.

Calculating efficiency for large open canal systems is extremely difficult. Hr'g Tr. vol. IV, at 146. TFCC's operation is enormous, with over 1,000 miles of canal, over 4,000 headgates, and over 10,000 concrete structures. Hr'g Tr. vol. II, at 16–18. Evaluating the efficiency of each mile of canal or headgate is a large undertaking. The Ground Water Users, the parties that bear the burden of proof, have not evaluated the SWC's canal and lateral efficiencies.

The Ground Water Users also contend the Director should instruct the Technical Working Group to "develop a mechanism to track real canal efficiency based on real efficiency factors." IGWA's Post-Hr'g Br., at 16. The Ground Water users' proposal attempts to misdirect the burden of proof. "[I]f the junior users believe for some reasons that the seniors will receive water they cannot beneficially use, it is their burden under the established evidentiary standards and burdens of proof to prove that fact by clear and convincing evidence." *2014 District Court Order*, at 31.

TFCC's general manager Jay Barlogi testified that his organization's diversions were reasonable and that TFCC worked hard to improve its efficiency, for example by annually cleaning its canals, lining canals, and replacing over 100 concrete structures per year. Hr'g Tr. vol. II, at 18–20. Mr. Shaw testified that TFCC does a good job maintaining its infrastructure compared to other water delivery organizations, and that TFCC's delivery system is reasonable. Hr'g Tr. vol. IV, at 146.

Lastly, the Ground Water Users imply TFCC is wasting significant quantities of water as evidenced by TFCC's return flows. Hr'g Tr. vol. II, at 191–196. For example, the Cities offered into evidence a document that purports to show TFCC's return flows from 2009–2022. Ex. 365.

Exhibit 365 does not distinguish between natural flow in tributary creeks (e.g., Rock Creek) from water TFCC diverted from the Snake and later returned to the Snake. This matters because measured flows can include irrigation returns as well as water from tributaries. Hr'g Tr. vol. II, at 241. The Cities' exhibit does not prove how much water TFCC diverted from the Snake and later returned.

Return flow data are difficult to obtain. Mr. Anders testified that the Department monitors some of TFCC's return flow, but does not monitor some of the smaller return flows. Hr'g Tr. vol. I, at 128. TFCC's general manager Jay Barlogi testified that he did not believe TFCC was returning a significant amount of water. Hr'g Tr. vol. II, at 43.

The SWC's surface water delivery systems were designed to divert large flow rates delivered to many farmers through long and complex networks of canals and laterals. At the beginning of the irrigation season, these networks must fill over the course of several days. The time needed to fill the canals has a relationship to the time necessary to respond to changes in delivery or emergency. If a large rainstorm reduces the demand for delivery of irrigation water in the canals and laterals, and many users along the delivery system reduce deliveries, the canal company cannot immediately reduce the water being delivered in its system at the diversion from the Snake River. Furthermore, the SWC entity also cannot immediately refill the canals and laterals when the rain stops and the crops demand an immediate water supply. Finally, an emergency on a canal or lateral, like a bank failure, might require that water in the delivery system be discharged from the canals to relieve the system of excess water.

The SWC entities must be able to discharge some water out of its system to ensure delivery of water to its patrons and to operate efficiently within the limits of the delivery system. Testimony at the hearing established that the SWC entities operated efficiently within the limits of their delivery system. *See* Hr'g Tr. vol. II, at 75, 90–91, 94–96; Hr'g Tr. vol. IV, at 146.

The Director concludes TFCC's diversions and efficiency are reasonable.

D. Curtailment

1. Transient vs. Steady-State Modeling

In previous years, the Director used steady-state modeling when determining the curtailment priority date.

In surface water administration, uses by holders of junior priority surface water rights are curtailed until the senior surface water rights are fully satisfied, absent a futile call and if the senior surface water users need the water to accomplish a beneficial use. Under surface water administration, junior surface water rights are generally curtailed unless the senior receives water in the quantity and at the time and place required.

As previously stated in *Am. Falls Reservoir Dist. No. 2*, 143 Idaho at 878, 154 P.3d at 449, "[t]he presumption under Idaho law is that the senior is entitled to his decreed water right . . . ." Entitlement to the decreed water right includes receiving water in the quantity and at the time and place required. The Director has a responsibility to respond timely to injury incurred by senior water users; there should be no unnecessary delays in that process. *Id.* "Clearly, a timely response is required when a delivery call is made and water is necessary to respond to that call." *Id.* This is common sense because "[i]n practice, an untimely decision effectively becomes the decision; i.e. 'no decision is the decision.'" Order on Pls.' Mot. for Summ. J., at 97, *Am. Falls Reservoir Dist. No. 2 v. Idaho Dep't of Water Res.*, No. CV-2005-600 (Gooding Cnty. Dist. Ct. Idaho June 2, 2006)

Rule 43 of the CM Rules mandates that when the Director evaluates a mitigation plan, the mitigation plan must ensure that water is delivered to holders of senior priority surface water rights in both the quantity and at the time and place required by the senior. In considering a proposed mitigation plan pursuant to Rule 43.03, the Director must evaluate:

> b. Whether the mitigation plan will provide replacement water, *at the time and place required by the senior-priority water right*, sufficient to offset the depletive effect of ground water withdrawal on the water available in the surface or ground water source *at such time and place as necessary* to satisfy the rights of diversion from the surface or ground water source. Consideration will be given to the history and seasonal availability of water for diversion so as not to require replacement water at times when the surface right historically has not received a full supply, such as during annual low-flow periods and extended drought periods.
>
> c. Whether the mitigation plan provides replacement water supplies or other appropriate compensation to the senior-priority water right *when needed during a time of shortage* even if the effect of pumping is spread over many years and will continue for years after pumping is curtailed. A mitigation plan may allow for multi-season accounting of ground water withdrawals and provide for replacement water to take advantage of variability in seasonal water supply. The mitigation plan must include contingency provisions to assure protection of the senior-priority right in the event the mitigation water source becomes unavailable.

IDAPA 37.03.11.043.03.b–c (emphasis added). In other words, there is an assumption that senior water right holders calling for delivery of water under the CM Rules will receive, by curtailment or by mitigation, "replacement water, at the time and place required by the senior priority water right, sufficient to offset the depletive effect of ground water withdrawal . . . ." The plan must "assure protection of the senior-priority right in the event the mitigation water source becomes unavailable."

The Director has an obligation to address a mitigation deficiency in the year it occurs. Mem. Decision & Order on Pet. for Jud. Rev., at 10, *Rangen, Inc. v. Idaho Dep't of Water Res.*, No. CV-2014-2446 (Twin Falls Cnty. Dist. Ct. Idaho Dec. 3, 2014); Mem. Decision & Order, at 8–9, *Rangen, Inc. v. Idaho Dep't of Water Res.*, No. CV-2014-4970 (Twin Falls Cnty. Dist. Ct. Idaho June 1, 2015).

Curtailment to a priority date calculated by the steady state analysis method used in the Fourth Methodology Order will only offset 9% to 15% of the predicted IDS. In contrast, curtailment to a priority date calculated with a transient simulation of a single season curtailment will offset the *full* predicted IDS unless the shortfall exceeds the accruals to the near Blackfoot to Minidoka reach by the end of the irrigation season with curtailment of all junior ground water rights. This methodology order depends on an annual evaluation of material injury and should also employ curtailment and or mitigation that supplies replacement water at the time and place required by the senior-priority water right in a quantity sufficient to offset the shortfall resulting from ground water withdrawal and to assure protection of the senior-priority right. Curtailment dates, periodically determined at time of recalculating in season demand shortfall (IDS), should be calculated by a transient model simulation that will return the full quantity of water to the senior priority rights at the time and place required, or the maximum quantity that can be returned by curtailing all junior water rights.

The Ground Water Users argue the Director should have determined a priority date for curtailment by steady state modeling of a continuous curtailment that would eventually deliver a volume of water to satisfy the demand shortfall of SWC entities, and require continuous mitigation from holders of ground water rights junior to the calculated priority date. Curtailment would be the threat to ensure the holders of junior ground water rights comply with the mitigation plan. This proposal, while lofty in its equitable ambition, does not follow the legal progression of water administration. In a delivery call proceeding in Idaho, the Director does not impose mitigation plans upon the holders of junior priority water rights. Mitigation plans are proposed by holders of junior priority ground water rights and may be approved by the Director to allow for out-of-priority pumping. Curtailment, or the threat of curtailment, is the tool employed by the Director to force the development of a mitigation plan. Only a threat of continuous curtailment of ground water rights bearing priority dates junior to some unknown priority date would prevent shortfalls to calling parties.

This argument fails because of extreme fluctuations in the Snake River flows caused by fluctuating flows from snowmelt, there are years when there is plentiful surface water for beneficial use and there is no material injury to the calling parties. Water may be flowing past Milner Dam, down the Snake River, and out of the State of Idaho. If there were a curtailment, these facts could be viewed as a waste of water, the antithesis of optimizing the beneficial use of the water of the State of Idaho.

Furthermore, when there is a demand shortfall, the magnitude of the shortfall varies. Choosing a single priority date for continuous curtailment to match one year's shortfall would be inaccurate.

As stated by the CM Rules and by the Courts, out of priority diversion is only allowed by an approved mitigation plan. Junior water right holders can develop or adhere to an approved mitigation plan to avoid curtailment in years of demand shortfalls and allow for out of priority diversions.

2. Futile Call

CM Rule 42.01.c alludes to delayed depletions caused by ground water pumping that affect the "quantity and timing" of water availability to the senior surface water rights. The Director must consider whether "the holders of [senior priority] water rights are suffering material injury" even though the full depletion is not immediate and may be delayed for multiple years:

> Whether the exercise of junior-priority ground water rights individually or collectively affects the quantity and timing of when water is available to . . . a senior-priority surface . . . water right. This may include the seasonal as well as the multi-year and cumulative impacts of all ground water withdrawals from the area having a common ground water supply.

CM Rule 42.01.c.

Delay in the depletive effect of ground water pumping is not grounds for the Ground Water Users to be excused from water administration under the CM Rules. If there is a significant depletion to the senior water rights, even if the impact is spread over multiple years, junior Ground Water Users are subject to water administration.

In support of this conclusion, CM Rule 43.03.c outlines a variety of factors the Director may consider in determining whether a proposed mitigation plan will prevent injury to senior rights including:

> Whether the mitigation plan provides replacement water supplies or other appropriate compensation to the senior-priority water right when needed during a time of shortage even if the effect of pumping is spread over many years and will continue for years after pumping is curtailed. A mitigation plan may allow for multi season accounting of ground water withdrawals and provide for replacement water to take advantage of variability in seasonal water supply. The mitigation plan must include contingency provisions to assure protection of the senior priority right in the event the mitigation water source becomes unavailable.

If the Director were to determine that curtailment of some ground water rights would not immediately accrue water to the senior priority surface water rights, even though the cumulative impact is significant, and that the delivery call is futile because there is no immediate benefit for the surface water rights, the holders of junior priority ground water rights could recurringly avoid curtailment. Avoiding obligation because of delayed cumulative impact is contrary to the intent of the CM Rules. The Director concludes the delivery call is not futile.

3. Trim line

Establishing a trim line is a close relative to determining a futile call. In the Rangen delivery call, the Director previously established a trim line when the cumulative benefits

of curtailment to a remote spring tributary to the Snake River were de minimus. On appeal, the Idaho Supreme Court stated:

> In light of this challenging balancing requirement, it is necessary that the Director have some discretion to determine in a delivery call proceeding whether there is a point where curtailment is unjustified because vast amounts of land would be curtailed to produce a very small amount of water to the caller. As discussed, Idaho law contemplates a balance between the "bedrock principles" of priority of right and beneficial use. *In Matter of Distribution of Water to Various Water Rights Held By or For Benefit of A & B Irrigation Dist.*, 155 Idaho 640, 650, 315 P.3d 828, 838 (2013). The Director is authorized to undertake this balancing act, subject, as he acknowledged here, to the limitations of Idaho law.

Idaho Ground Water Assoc. v. Idaho Dep't of Water Res., 160 Idaho 119, 132, 369 P.3d 897, 910 (2016).

The spatial distribution of long-term impacts of Ground Water Users on aquifer discharge to the near Blackfoot to Minidoka reach is documented in the record. In Ms. Sigstedt's expert report, Figure 3-6 shows the steady state response function, which is the long-term impact of pumping on the near Blackfoot to Minidoka reach as a percentage of the volume of ground water used. Ex. 837 at 38. Figure 3-6 shows that Ground Water Users on both sides of the Great Rift (the boundary applied to the Rangen delivery call trim line) have significant long-term impacts on aquifer discharge to the nB-Min reach. As a result, the Director concludes that a trimline is not appropriate.

4. Model Uncertainty

Prior to the issuance of the Fifth Methodology Order and 2023 April As-Applied Order, three versions of ESPAM (1.1, 2.1, and 2.2) quantified depletions to surface water supply caused by junior ground water pumping or calculated priority dates for curtailment for this delivery call. These three model versions have also quantified depletions to surface water supply caused by ground water pumping in support of water right administration, including the approval or denial of water right transfer applications. In transfer evaluations, the current and previous versions of ESPAM have calculated the transient impacts of ground water pumping on Snake River reach gains, similar to the transient calculation of curtailment benefit implemented in the Fifth Methodology Order and 2023 April As-Applied Order. Ex. 3, at 7.

The current version, ESPAM version 2.2 was completed in May 2021 and superseded ESPAM version 2.1 as the best available scientific tool for these purposes. Improved representation of ground water and surface water interaction in the near Blackfoot to Neeley reach was identified as one of the priorities for development of ESPAM version 2.2 and significant improvements to the Department's monitoring network and the ESPAM model were implemented with the guidance of the Eastern Snake Hydrologic Modeling Committee to achieve this objective. Off. Noticed Doc. ModelCalibration22_Final, at 1, 3; Off. Noticed Doc.

CurtScen22_FinalwApp, at 10.[10] A predictive uncertainty analysis of ESPAM version 2.2 was performed and presented to the Eastern Snake Hydrologic Modeling Committee in conjunction with the release of the new version. Off. Noticed Doc. E22PredUnc_Final.[11]

While the predictive uncertainty analysis did not specifically quantify the uncertainty of the model predictions applied in the 2023 April As-Applied Order, it does provide a general understanding of the contribution of model calibration to predictive uncertainty for steady-state and transient model scenarios. *Id.* at 41. Model uncertainty is not so significant to suggest that a transient simulation of a single season curtailment will not provide a more accurate estimate of the increase in reach gains expected to occur during the current irrigation season than a steady-state simulation of a continuous curtailment. In other words, there is no evidence that model uncertainty is so significant that a curtailment date calculated using a steady-state simulation, which results in a predicted in-season accrual of approximately 10% of the IDS, could possibly result in an actual in-season accrual approaching 100% of the IDS.

Further, any administrative allowance for uncertainty in the prediction of the volume of water obtained by applying a given curtailment date would be applied to reduce the risk to the senior water user and would result in applying an earlier curtailment date. Because of the safety factor already applied in the calculation of the shortfall, the Director does not find that an additional safety factor needs to be applied to calculation of the priority date. Further, the senior water users did not request that the Director add an additional safety factor to account for ESPAM predictive uncertainty.

E. Due process

The Ground Water Users contend the Department violated their due process rights and the Idaho Administrative Procedures Act by issuing the methodology order before holding a hearing, and by failing to provide the Ground Water Users sufficient time to prepare for the hearing. IGWA's Post-Hr'g Br., at 18. The Ground Water Users are mistaken.

Idaho Code § 42-1701A governs hearings before the Director, and provides among other things that:

> Unless the right to a hearing before the director . . . is otherwise provided by statute, any person aggrieved by any action of the director, including any decision, determination, order or other action, including action upon any . . . approval . . . or similar form of permission required by law to be issued by the director, who is aggrieved by the action of the director, and who has not previously been afforded

[10] Available for download at https://idwr.idaho.gov/legal-actions/delivery-call-actions/SWC/, "Materials Department Witnesses May Rely Upon at Hearing—May 5, 2023". Downloaded folder pathways: ESPAM Report\ESPAM22_Reports\ ModelCalibrationRpt \ ModelCalibration22_Final; ESPAM Report\ESPAM22_Reports\Scenarios\ CurtScen22_FinalwApp.

[11] Available for download at https://idwr.idaho.gov/legal-actions/delivery-call-actions/SWC/, "Materials Department Witnesses May Rely Upon at Hearing—May 5, 2023". Downloaded folder pathway: ESPAM Report\ESPAM22_Reports\ESPAM22_Reports\UncertaintyRpt\ E22PredUnc_Final.

an opportunity for a hearing on the matter shall be entitled to a hearing before the director to contest the action.

The Methodology Order constitutes an "order" under § 42-1701A(3), meaning there is no statutory right to a pre-decision hearing concerning an amendment to the Methodology Order. The Idaho Supreme Court has already held that "[t]he Director may develop and implement a pre-season management plan for allocation of water resources that employs a baseline methodology . . . [and is] made available in advance of the applicable irrigation season . . . ." *In Matter of Distribution of Water to Various Water Rts. Held By or For Ben. of A & B Irrigation Dist*., 155 Idaho at 653, 315 P.3d at 841.

The Idaho Supreme Court has also clearly expressed that the Director has a legal responsibility to *timely* respond to injury incurred by senior water users. Am. Falls Reservoir Dist. No. 2, 143 Idaho at 874, 154 P.3d at 445. The District Court has already ruled in this matter that the process the Department afforded "provides due process consistent with the exigencies of the circumstances and the director's duty to timely administer water rights in priority. And frankly, setting a hearing after the irrigation season as requested is not a tangible alternative . . . ." Excerpt from Hr'g on Admin. Appeals (Court's Ruling) Tr., at 8–9, *City of Pocatello v. Idaho Dep't of Water Res.*, No. CV01-23-08258 (Ada Cnty. Dist. Ct. Idaho June 1, 2023).

In sum, the Ground Water Users' due process rights were not violated, which the District Court has already determined.

ORDER

IT IS HEREBY ORDERED that the Director affirms the Fifth Methodology Order with a few modifications. Because there are some modifications, the Director will simultaneously issue with this order a *Sixth Final Order Regarding Methodology for Determining Material Injury to Reasonable In-Season Demand and Reasonable Carryover*.

DATED this 19th day of July 2023.

Gary Spackman
Director

CERTIFICATE OF SERVICE

I HEREBY CERTIFY that on this 19th day of July 2023, the above and foregoing, was served by the method indicated below, and addressed to the following:

EXPLANATORY INFORMATION TO ACCOMPANY A FINAL ORDER

(Required by Rule of Procedure 740.02)

The accompanying order is a "**Final Order**" issued by the department pursuant to section 67-5246 or 67-5247, Idaho Code.

Section 67-5246 provides as follows:

(1) If the presiding officer is the agency head, the presiding officer shall issue a final order.

(2) If the presiding officer issued a recommended order, the agency head shall issue a final order following review of that recommended order.

(3) If the presiding officer issued a preliminary order, that order becomes a final order unless it is reviewed as required in section 67-5245, Idaho Code. If the preliminary order is reviewed, the agency head shall issue a final order.

(4) Unless otherwise provided by statute or rule, any party may file a petition for reconsideration of any order issued by the agency head within fourteen (14) days of the service date of that order. The agency head shall issue a written order disposing of the petition. The petition is deemed denied if the agency head does not dispose of it within twenty-one (21) days after the filing of the petition.

(5) Unless a different date is stated in a final order, the order is effective fourteen (14) days after its service date if a party has not filed a petition for reconsideration. If a party has filed a petition for reconsideration with the agency head, the final order becomes effective when:

(a) The petition for reconsideration is disposed of; or
(b) The petition is deemed denied because the agency head did not dispose of the petition within twenty-one (21) days.

(6) A party may not be required to comply with a final order unless the party has been served with or has actual knowledge of the order. If the order is mailed to the last known address of a party, the service is deemed to be sufficient.

(7) A non-party shall not be required to comply with a final order unless the agency has made the order available for public inspection or the nonparty has actual knowledge of the order.

(8) The provisions of this section do not preclude an agency from taking immediate action to protect the public interest in accordance with the provisions of section 67-5247, Idaho Code.

PETITION FOR RECONSIDERATION

Any party may file a petition for reconsideration of a final order within fourteen (14) days of the service date of this order as shown on the certificate of service. **Note: the petition must be received by the Department within this fourteen (14) day period.** The department will act on a petition for reconsideration within twenty-one (21) days of its receipt, or the petition will be considered denied by operation of law. See section 67-5246(4) Idaho Code.

APPEAL OF FINAL ORDER TO DISTRICT COURT

Pursuant to sections 67-5270 and 67-5272, Idaho Code, any party aggrieved by a final order or orders previously issued in a matter before the department may appeal the final order and all previously issued orders in the matter to district court by filing a petition in the district court of the county in which:

i. A hearing was held,
ii. The final agency action was taken,
iii. The party seeking review of the order resides, or
iv. The real property or personal property that was the subject of the agency action is located.

The appeal must be filed within twenty-eight (28) days: a) of the service date of the final order, b) the service date of an order denying petition for reconsideration, or c) the failure within twenty-one (21) days to grant or deny a petition for reconsideration, whichever is later. See section 67-5273, Idaho Code. The filing of an appeal to district court does not in itself stay the effectiveness or enforcement of the order under appeal.

BEFORE THE DEPARTMENT OF WATER RESOURCES

OF THE STATE OF IDAHO

IN THE MATTER OF DISTRIBUTION OF WATER TO VARIOUS WATER RIGHTS HELD BY OR FOR THE BENEFIT OF A&B IRRIGATION DISTRICT, AMERICAN FALLS RESERVOIR DISTRICT #2, BURLEY IRRIGATION DISTRICT, MILNER IRRIGATION DISTRICT, MINIDOKA IRRIGATION DISTRICT, NORTH SIDE CANAL COMPANY, AND TWIN FALLS CANAL COMPANY	Docket No. CM-DC-2010-001 **NOTICE THAT QUESTIONS CONCERNING THE SUFFICIENCY OF IGWA'S MITIGATION NOTICES ARE MOOT**

BACKGROUND

On April 21, 2023, the Director of the Idaho Department of Water Resources ("Department") issued his *Fifth Amended Final Order Regarding Methodology for Determining Material Injury to Reasonable In-Season Demand and Reasonable Carryover* ("Methodology Order"). Step 3 of the Methodology Order states that by May 1, or within fourteen days from issuance of a final order predicting a shortfall, "junior ground water users with approved mitigation plans for delivery of water must secure, to the satisfaction of the Director, a volume of water equal to their proportionate share" of any predicted shortfall. *Methodology Order* at 40.

On April 21, 2023, the Director also issued his *Final Order Regarding April 2023 Forecast Supply* ("April 2023 As-Applied Order"), wherein the Director predicted the Twin Falls Canal Company ("TFCC") would suffer a 75,200 acre-feet shortfall. *April 2023 As-Applied Order* at 3. To ensure TFCC was protected, the Director ordered that on or before May 5, 2023:

> [G]round water users holding consumptive water rights bearing priority dates junior to December 30, 1953, within the Eastern Snake Plain Aquifer area of common ground water supply shall establish, to the satisfaction of the Director, that they can mitigate for their proportionate share of the predicted [demand shortfall] of 75,200 acre-feet in accordance with an approved mitigation plan. If a junior ground water user cannot establish, to the satisfaction of the Director, that they can mitigate for their proportionate share of the predicted [demand shortfall] of 75,200 acre-feet in accordance with an approved mitigation plan, the Director will issue an order curtailing the junior-priority ground water user.

April 2023 As-Applied Order at 6.

On May 5, 2023, the Idaho Ground Water Appropriators, Inc. ("IGWA"), acting on behalf of certain water districts[1] (collectively the "Districts"), filed a *Notice of Ground Water District Mitigation* ("Mitigation Notice").

IGWA's *Mitigation Notice* explained that "IGWA has three approved mitigation plans." *Mitigation Notice* at 2. IGWA asserted its first plan (the "2009 Storage Water Mitigation Plan") authorized the Districts to mitigate by delivering storage water to the Surface Water Coalition ("SWC"). *Id*. IGWA contends its second plan (the "Aquifer Enhancement Plan") authorized the Districts to "obtain mitigation credit" for various activities, e.g., fallowing acres irrigated by groundwater. *Id*. IGWA asserted its third plan (known as the "2015 Settlement Agreement Mitigation Plan") authorized the Districts to "obtain mitigation protection by complying with a 2015 settlement agreement between the Districts and the SWC. *Id*.

IGWA then advised that certain districts intended to mitigate under the 2009 Storage Water Mitigation Plan, while other districts intended to mitigate under the 2015 Settlement Agreement Mitigation Plan. *Id*. at 2–3.

On May 23, 2023, the Director issued an *Order Determining Deficiency in IGWA's Notice of Secure Water* ("Deficiency Order"). Of import here, the Director concluded IGWA's *Mitigation Notice* was deficient as it was improper for some Districts to mitigate under the 2009 Storage Water Mitigation Plan while others mitigated under the 2015 Settlement Agreement Mitigation Plan. *Deficiency Order* ¶¶ 2, 7, 9, 20, 21. The Director also determined IGWA's *Mitigation Notice* was deficient given IGWA's failure to tender fees to Water District 01 along with proof of legally enforceable contracts as required under the 2009 Storage Water Mitigation Plan. *Deficiency Order* ¶¶ 8, 9.

On June 1, 2023, IGWA submitted *IGWA's Amended Notice of Mitigation* ("Amended Mitigation Notice"), advising that IGWA would mitigate under the 2009 Storage Water Mitigation Plan. *Amended Mitigation Notice* at 3. IGWA also attached "copies of storage lease contracts secured by IGWA's member ground water districts totaling 77,714 acre-feet." *Id.*; *see also Amended Mitigation Notice* app. A. IGWA also objected to the Director's requiring IGWA to pay Water District 01's fees, but advised it had paid the fees notwithstanding its objection. *Amended Mitigation Notice* at 3.

On June 5, 2023, the SWC submitted *Surface Water Coalition's Response to IGWA's Amended Notice of Mitigation* ("SWC's Response"). The SWC argues IGWA's *Amended Mitigation Notice* is unclear whether IGWA members are agreeing to mitigate only for their proportionate shares, or instead for all ground water users as mandated under the 2009 Storage Water Mitigation Plan. *SWC's Response* at 2. The SWC further argues that IGWA's *Amended Mitigation Notice* fails to "address all of IGWA's storage water mitigation obligations for 2023", which include additional requirements beyond those articulated in the 2009 Storage Water Plan. *Id*. at 2–3.

[1] IGWA's submitted the Notice of Mitigation on behalf of: North Snake Ground Water District, Carey Valley Ground Water District, Magic Valley Ground Water District, Aberdeen-American Falls Ground Water District, Bingham Ground Water District, Bonneville-Jefferson Ground Water District, Jefferson-Clark Ground Water District, Madison Ground Water District, and Henry's Fork Ground Water District. *Mitigation Notice* at 1.

On June 6, 2023, IGWA submitted a *Petition for Reconsideration of Order Determining Deficiency in IGWA's Notice of Secured Water* ("Petition for Reconsideration"), wherein IGWA requested that the Director "withdraw the new requirement that Water District 1 fees be paid before the Director will accept signed storage water lease or option contracts as proof of IGWA's ability to provide storage water as mitigation." *Petition for Reconsideration* at 1.

Also on June 6, 2023, IGWA submitted its *Reply to SWC's Response to IGWA's Amended Notice of Mitigation* ("IGWA's Reply"). In its reply, IGWA argued it was not required to mitigate for all ground water users under the 2009 Mitigation Plan, and further argued it was in compliance with all its mitigation obligations. *IGWA's Reply* at 2.

On June 12, 2023, the SWC submitted *Surface Water Coalition's Response to IGWA's Reply* ("SWC's Response to IGWA's Reply"). The SWC reiterated that "[i]f IGWA is relying on the [2009 Mitigation Plan] to mitigate, it must mitigate for all ground water users, not just its members . . . ." *SWC Response to IGWA's Reply* at 2. The SWC emphasized that "IGWA cannot ignore the comprehensive terms of the Settlement Agreement Plan and mitigate only with the [2009] Storage Water Mitigation Plan to satisfy its 2023 obligation." *Id*. at 5. The SWC also reiterated that IGWA must supply an additional 30,000 acre-feet in 2023 as a remedy for IGWA's breach in 2021. *Id*. 2–3.

On July 19, 2023, the Director issued the Department's *Sixth Final Order Regarding Methodology for Determining Material Injury to Reasonable In-Season Demand and Reasonable Carryover*, as well an *Order Revising April 2023 Forecast Supply (Methodology Steps 5 & 6)* ("July 2023 As-Applied Order"). Of import here, in the *July 2023 As-Applied Order* the Director concluded that members of the SWC will not suffer a demand shortfall in 2023. *July 2023 As-Applied Order* at 9.

ANALYSIS

A matter "is moot if it presents no justiciable controversy and a judicial determination will have no practical effect upon the outcome." *Goodson v. Nez Perce Cnty. Bd. of Cnty. Comm'rs*, 133 Idaho 851, 853, 993 P.2d 614, 616 (2000). As noted above, the Director recently issued the July 2023 As-Applied Order, which found that no SWC members would suffer a demand shortfall in 2023. Because there is no demand shortfall, ground water users are no longer required to mitigate. Since ground water users are no longer required to mitigate, questions regarding the sufficiency of IGWA's *Mitigation Notice* or *Amended Mitigation Notice* no longer present a justiciable controversy and are therefore moot.

NOTICE

Having concluded that questions concerning the sufficiency of IGWA's mitigation notices are moot, the Director provides notice that the Department will not issue orders responding to *IGWA's Petition for Reconsideration of Order Determining Deficiency in IGWA's Notice of Secured Water* or *IGWA's Amended Notice of Mitigation*.

Dated this 20th day of July 2023.

GARY SPACKMAN
Director

Attorneys for American Falls Reservoir District #2 and Minidoka Irrigation District

BEFORE THE DEPARTMENT OF WATER RESOUCES

OF THE STATE OF IDAHO

IN THE MATTER OF DISTRIBUTION OF WATER TO VARIOUS WATER RIGHTS HELD BY OR FOR THE BENEFIT OF A&B IRRIGATION DISTRICT, AMERICAN FALLS RESERVOIR DISTRICT #2, BURLEY IRRIGATION DISTRICT, MILNER IRRIGATION DISTRICT, MINIDOKA IRRIGATION DISTRICT, NORTH SIDE CANAL COMPANY, AND TWIN FALLS CANAL COMPANY	Docket No. CM-DC-2010-001 CM-MP-2016-001 **SURFACE WATER COALITION'S PETITION FOR RECONSIDERATION & CLARIFICATION** **REQUEST FOR ENFORCEMENT OF ORDERS APPROVING 2016 STIPULATED PLAN**

COME NOW, A&B IRRIGATION DISTRICT, AMERICAN FALLS RESERVOIR DISTRICT #2, BURLEY IRRIGATION DISTRICT, MILNER IRRIGATION DISTRICT, MINIDOKA IRRIGAITON DISTRICT, NORTH SIDE CANAL COMPANY, and TWIN FALLS CANAL COMPANY ("Surface Water Coalition" or "Coalition"), by and through counsel of record, and pursuant to I.C. § 67-5246(4) and IDAPA 37.01.01.740.02.a and 770, hereby submits this petition for reconsideration and clarification concerning the Director's *Order Revising April*

2023 Forecast Supply and Amending Curtailment Order ("Step 5/6 Order") and the *Notice that Questions Concerning the Sufficiency of IGWA's Mitigation Notices are Moot* ("Notice").

The Coalition further requests that the Director address IGWA's 2022 breach of the 2016 mitigation plan and enforce the orders approving the same.

BACKGROUND

On March 9, 2016, the Surface Water Coalition and the nine signatory ground water districts (hereinafter collectively "IGWA") filed a *Stipulated Mitigation Plan and Request for Order* ("*Stipulated Plan*") regarding mitigation in this delivery call. The Director approved the plan by final order on May 2, 2016. The history of that plan and order, and what is required under both, are set forth in the Director's recent *Amended Final Order Regarding Compliance with Approved Mitigation Plan* ("Compliance Order") issued on April 24, 2023.[1]

On April 1, 2023, IGWA submitted its 2022 performance report to the Coalition and the Steering Committee. The Committee met on April 12, 2023 and disagreed on whether or not IGWA breached the agreement and mitigation plan in 2022. The Coalition reported the impasse to the Director by letter. *See* Ex. A (*Travis L. Thompson Letter to Director Spackman*, April 13, 2023). Pursuant to the terms of the *Stipulated Plan* and its amendments, following such notification, resolving the issue of whether a breach occurred and expediting resolution was turned over to the Director.

IDWR completed its review of IGWA's annual performance report on June 29, 2023. According to IDWR, IGWA only completed 188,095 acre-feet of conservation actions in 2022, well short of the required 240,000 acre-feet. *See* Ex. B (*IDWR Verification Memo*, June 29, 2023).

[1] IGWA has appealed this order to district court, but the order remains in effect and has not been stayed by the agency or the court. *See generally*, *IGWA v. IDWR* (Ada County Dist. Ct., Fourth Jud. Dist., Case No. CV01-23-7893).

The Director indicated that he would not address curtailment or the 2022 breach issue until after the administrative hearing concerning the *Fifth Methodology Order* and *April As Applied Order* was completed. That hearing was held before the agency on June 6-9, 2023. The Director further initially addressed IGWA's attempted "hybridization" of mitigation plans and indicated there were "serious questions about whether mixing of mitigation plans is allowable and whether there is compliance with a mitigation plan at all." *See Order Denying Motion for Reconsideration of Denial of Continuance* (May19, 2023). Since that time IGWA has assigned the following to the Surface Water Coalition through letters to Water District 01: 30,000 acre-feet for purposes of the 2022 Settlement regarding the 2021 breach (*see T.J. Budge July 10, 2023 Letter to Tony Olenichak*); and 50,000 acre-feet (*see Elisheva Patterson July 21, 2023 Letter to Tony Olenichak*). *See* Ex. C (copies of letters without leases).

On July 19, 2023 the Director issued the Step 5/6 Order and the Notice. The mid-season evaluation predicted no in-season demand shortfall to any Coalition member. Consequently, the Director stated "there is no need to establish a Time of Need as described in Step 6." In addition, in the Notice the Director stated "[b]ecause there is no demand shortfall, ground water users are no longer required to mitigate." Notice at 3. The Coalition requests reconsideration and clarification of these statements and requests the Director to address IGWA's 2022 breach as required under the *Second Addendum* and the May 2017 Order approving the same.

ARGUMENT

I. IGWA Has a Continuing Obligation to Annually Mitigate Under the 2016 Stipulated Plan and Orders Approving the Same.

The Director's implementation of the methodology order and mid-season review under Steps 5/6 does not obviate IGWA's obligation to mitigate under the *Stipulated Plan* and the Director's orders approving the same. Although IGWA recently assigned 50,000 acre-feet as

required, there are serious questions as to whether the individual groundwater districts are complying with the remaining long-term obligations as agreed to and ordered by the Director.

Notably, only five districts provided notice of their intent to comply with the 240,000 acre-feet groundwater conservation requirement in 2023. *See Notice of Ground Water District Mitigation* at 2 (May 5, 2023). Members of the Bingham, Bonneville-Jefferson, and Jefferson-Clark Ground Water Districts are presumably not complying with that requirement but yet are continuing to pump their junior priority ground water rights in 2023 without the required reductions, as they apparently did in 2022. IGWA has not formally provided the Director and the Coalition with any information that would indicate otherwise. Whereas the mitigation requirements in the *Stipulated Plan* are not dependent upon an injury finding in the implementation of the methodology order, the Director should reconsider the statement and review of IGWA's mitigation notices. In sum, there is no verification that IGWA is complying with its stipulated mitigation plan and the Director's orders as set forth in the *Compliance Order*.

As such, the Director should reconsider or clarify the statement that "ground water users are no longer required to mitigate," particularly to the extent that statement may be interpreted to obviate any requirements under the *Stipulated Plan* and orders.

II. Implementation of Step 7 May Result in an In-Season Demand Shortfall.

The *Sixth Methodology Order* requires the Director to analyze and adjust the reasonable in-season demand and available water supply at the "time of need." *See* Sixth Order at 44. Further, the order states that "The Director will then issue revised RISD and IDS values." *Id.* The Step 5/6 Order states "there is no need to establish a Time of Need." *See* Step 5/6 Order at 9. When that statement is read together with the above (i.e. "ground water users are no longer required to mitigate"), it is unclear what the Director intends for the rest of the irrigation season.

At a minimum, the Director should reconsider or clarify this statement to provide the parties with notice that this statement is not definitive for the rest of the 2023 irrigation season, and that additional adjustments may be made depending upon climatic conditions and available water supplies. Given the state of Snake River reach gains in July, the available supply for natural flow for the rest of the year is likely to be far less than what was identified in the forecast supply in the Step 5/6 Order. In other words, the Coalition presumes that a "time of need" will be established at some point and that Step 7 will be implemented as required by the Sixth Order. Moreover, such clarification would be necessary and consistent with mitigation being provided "in-time, in-place, and in-kind."

III. Request for Enforcement of Orders Approving 2016 Stipulated Plan.

Given the April impasse of the Steering Committee, and IDWR's recent verification of IGWA's failure to perform as required in 2022, the Coalition requests the Director to enforce the orders approving the *Stipulated Plan* and its amendments.

Since the parties did not agree on whether or not a breach occurred in 2022, and the Director has been notified of such impasse, the Director should evaluate all available information and determine if a breach occurred, and issue an order specifying what actions that must be taken to cure the breach. *See Final Order Approving Amendment to Stipulated Mitigation Plan* at 5, ¶ b (identifying approval does not limit Director's enforcement discretion). The Districts' failure to perform in 2022, and at least the apparent uncertainty of whether the three districts are performing at all in 2023, is contributing to declining Near Blackfoot to Milner Snake River reach gains (which dropped to their lowest ever recorded levels in July). Given certain ground water districts' failure to perform in 2022, their members with junior priority ground water rights are not operating in conformance with their stipulated plan. Consequently, the Director has an

obligation to evaluate this information and take action as referenced in the September 2022 *Compliance Order*:

> In this case, certain holders of junior-priority water rights failed to satisfy their mitigation obligations in 2021. Out-of-priority diversions by the IGWA members in Table 3 above were not "pursuant to a mitigation plan that has been approved by the Director." IDAPA 37.03.11.040.01.b. The approved Mitigation Plan was not "effectively operating" with respect to those IGWA members in 2021. IDAPA 37.03.11.042.02. Consequently, the holders of senior water rights have been and are being materially injured by the failure of the juniors to fully mitigate during the 2021 irrigation season.

Compliance Order at 15.

Whereas the Coalition previously agreed to limit the quantity of direct storage mitigation to 50,000 acre-feet per year in exchange for the additional reduction actions (240,000 af), it is clear now that IGWA is not complying with its mitigation plan but yet its members are still enjoying the benefits of safe harbor from curtailment. Further, when viewed in the context of IGWA not meeting the spring 2023 sentinel well benchmark, the continued disparity in the receipt of benefits of the *Stipulated Plan* is even more apparent. Reach gains continue to decline year after year yet ground water users continue to pump their junior rights without shortage. If the Director does not enforce the ordered conservation obligations, then the Surface Water Coalition's stipulation to 2016 mitigation plan was all for naught, and it effectively turns the prior orders into a "storage only" mitigation requirement to the detriment of the Coalition and its water supply.

Stated another way, IGWA should not be permitted to "mix and match" mitigation plans, and choose to comply with a prior "storage only" plan in years when there is no predicted demand shortfall. Yet that is what IGWA has proposed to do in 2023, and the issue of whether or not that is allowed is not "moot." Finally, where IGWA's members have received safe harbor

in 2022 and 2023, yet they are not in compliance with the *Stipulated Plan*, the Director should evaluate the available information and enforce the orders as previously indicated.

CONCLUSION

The Coalition requests reconsideration/clarification of the Step 5/6 Order and Notice as requested above. The Coalition further requests enforcement of the Director's prior orders approving the *Stipulated Plan* and its amendments.

DATED this 31st day of July, 2023.

P.O. Box 83720
Boise, Idaho 83720-0098

RE: Ground Water Districts' 2022 Performance Report / Steering Committee Meeting

Dear Director Spackman:

I am writing on behalf of our Surface Water Coalition clients (A&B et al.) and am joined by Kent Fletcher on behalf of his Coalition clients (AFRD#2 & MID) and T.J Budge on behalf of his ground water district clients (Districts). This letter pertains to the Coalition's delivery call and the Districts' stipulated mitigation plan (including addendums) that was approved by you by final orders in 2016 and 2017.

For your information, the Districts submitted their 2022 implementation report to the Coalition on April 1, 2023, a copy of which is enclosed as Exhibit A. The Coalition met and reviewed the report, and, based on the conservation obligations set by the Director in the *Final Order Regarding Compliance with Approved Mitigation Plan* issued Sept. 8, 2022 ("Compliance Order"), I submitted a letter on behalf of the Coalition to the Districts' counsel on April 6, 2023, identifying certain Districts that did not meet their 2022 obligations. *See* Exhibit B.

The Coalition met with the Districts via Zoom on April 12, 2023 pursuant to the Steering Committee procedures identified in the *Second Addendum* and the Director's order approving the same. The Coalition submits that the four Districts identified in my April 6th letter breached the mitigation plan and the Director's order in irrigation season 2022. Pursuant to the *Second Addendum* paragraph 2(c), the Coalition asked the Districts if they agree that a breach occurred.

The Districts are of the position that they can neither agree nor disagree that a breach occurred in 2022, or to the magnitude of the alleged breach, until the Director issues a final decision on their challenge to the *Compliance Order* based on the evidence submitted at the hearing held February 8, 2023. It is the Districts' position that the Director's final decision will in any case affect the manner in which compliance is measured, as explained in the Districts' performance report.

D – 208 . 735 . 2227 | E - tthompson@martenlaw.com | P.O. Box 63, Twin Falls, ID 83303-0063

MARTEN LAW

At the April 12th Steering Committee meeting, the Districts requested that the breach issue be tabled until the Director issues a final decision on the *Compliance Order*. However, the Coalition is not willing to table the matter for an indefinite period. Therefore, the Coalition submits that a breach occurred in 2022 and the Districts' disagree.

Pursuant to the Second Addendum paragraph 2(c)(iv) attached to the *Final Order Approving Amendment to Stipulated Mitigation Plan* dated May 9, 2017, when the parties do not agree that a breach has occurred, the Steering Committee will report the same to the Director and request that the Director evaluate all available information, determine if a breach has occurred, and issue an order specifying actions that must be taken by the breaching party to cure the breach or be subject to curtailment.

Thank you for your attention to this matter.

Sincerely,

Travis Thompson

June 29, 2023

To: **SWC-IGWA Steering Committee**
From: **Idaho Department of Water Resources**
Re: **Verification of IGWA's 2022 Diversion and Recharge Data**

This document is submitted by the Idaho Department of Water Resources ("Department") to the Surface Water Coalition ("SWC") and Idaho Ground Water Appropriators ("IGWA") Settlement Agreement Steering Committee to satisfy Covenant 2.b.iii of the Second Addendum to the Settlement Agreement ("Agreement") dated December 14, 2016 which states:

"The Parties will request the Department to verify each District's annual diversion volume, and other reduction data (recharge, CREP, conversions, end-gun removals, etc.) to confirm the accuracy of the data. The Department's analysis shall be provided to the Steering Committee no later than July 1 for the previous irrigation season."

On April 1, 2023, IGWA submitted their 2022 Settlement Agreement Performance Report ("Performance Report") to the Steering Committee. The Department has reviewed the Performance Report including electronic Excel spreadsheets, data tables and supplemental scanned documents. Data for each ground water district in the Performance Report included the five-year average baseline usage from 2010 through 2014, the total 2022 diversion volume, and the resultant difference between the five-year average baseline and 2022 diversion volume. These values are reported in column 2 of Tables 1, 2 and 3 in this memo. The five-year average baseline and 2022 diversion volume data came from the Department's Water Management Information System ("WMIS") database. IGWA adjusted the five-year average baseline and 2022 diversion volume for some WMIS records and explained the adjustments in their Excel spreadsheet.

Department staff independently queried the five-year average baseline and 2022 diversion volumes from the WMIS database for each WMIS record reported by IGWA to compare against the five-year average baseline and 2022 diversion volume amounts contained in the Performance Report. This was done to capture revisions to historic data in WMIS and account for membership changes within the ground water districts. Data resulting from these queries are reported by ground water district and shown in column 3 of Tables 1 and 2. The 2022 diversion volume reduction from the five-year baseline average is shown in column 3 of Table 3.

Some wells in Henry's Fork Ground Water District ("HFGWD") and Fremont Madison Irrigation District ("FMID") do not have a WMIS record assigned to them because they are exchange wells measured and reported by Water District 01 ("WD01"). Regarding HFGWD, IGWA and Department staff retrieved FMID data and Teton River exchange well data from the WD01 Water Rights Accounting database available on the Department's website. WD31 data, which are included in the reported volumes for Jefferson-Clark Ground Water District, were obtained from the 2022 WD31 Watermaster Annual Report.

The Department also attempted to verify IGWA's reported private lease-rental recharge amounts for the 2022 calendar year. Confirmation of actual recharge volumes is difficult due to the complexity of tracking surface water deliveries, transactions and return flow amounts to the Snake River. Therefore, the Department's review is limited to confirming the existence and delivery volumes of private lease-rental contracts within WD01, Temporary Water Permits, Natural Flow Permits and Water Supply Bank Rentals.

The following tables summarize the five-year average baseline, 2022 diversion volume, resultant reductions, and recharge contract volumes as determined by IGWA and the Department. The verification results are presented objectively with no assumption as to which dataset is correct or incorrect. Notes are provided under each table explaining additional details specific to that particular table or dataset. Possible explanations are offered regarding differences between IGWA and Department datasets.

The Department did not review or include data for A&B Irrigation District or the Southwest Irrigation District. The Department will consider reporting data for these districts to the Steering Committee upon request.

Table 1: Five-Year Baseline Comparison

2010 through 2014

1	2	3	4
Ground Water District	**IGWA Reported 5-Yr Baseline (AF)**	**IDWR Database 5-Yr Baseline (AF)**	**IDWR % Difference Compared to IGWA (negative = IDWR < IGWA)**
American Falls -Aberdeen GWD	283,815	282,200	-0.6
Bingham GWD	277,011	277,359	0.1
Bonneville - Jefferson GWD	158,133	155,292	-1.8
Carey Valley GWD	5,671	5,484	-3.3
Henry's Fork GWD	73,901	73,340	-0.8
Jefferson - Clark GWD	445,393	445,144	-0.1
Madison GWD (estimated data)	78,095	79,134	1.3
Magic Valley GWD	256,188	256,561	0.1
North Snake GWD	208,795	203,541	-2.5
Total	1,787,002	1,778,055	-0.5

Table 1 Notes:

- Madison GWD: Baseline data determined by IGWA and IDWR via the method described on the "Madison GWD" tab of the IGWA submittal Excel spreadsheet. The average usage for each diversion from 2019 and 2020 was estimated to be 92% of the baseline volume. The average use in 2019/2020 for each well was increased by a factor of 1.0869565 to get to a 100% baseline volume. IGWA estimated the 92% value by comparing usage in the adjoining Henry's Fork GWD area.
- Henry's Fork GWD: IGWA's revised the baseline volume in their April 1 report from 69,979 acre-feet to 73,901 acre-feet.
- Both the IGWA and IDWR baseline volume for North Snake included a volume of 21,305 acre-feet of conversions

Table 2: 2022 Usage Volume Comparison

1	2	3	4
Ground Water District	**IGWA Reported Usage (AF)**	**IDWR Database Usage (AF)**	**IDWR % Difference Compared to IGWA (negative = IDWR < IGWA)**
American Falls -Aberdeen GWD	269,322	269,197	0.0
Bingham GWD	269,088	268,126	-0.4
Bonneville - Jefferson GWD	151,245	150,996	-0.2
Carey Valley GWD	1,889	1,447	-23.4
Henry's Fork GWD	65,177	66,780	2.5
Jefferson - Clark GWD	408,112	408,308	0.0
Madison GWD	76,919	75,939	-1.3
Magic Valley GWD	218,759	218,721	0.0
North Snake GWD	174,838	174,710	-0.1
Total:	1,635,349	1,634,224	-0.1

Table 2 Notes:

- Carey Valley GWD: Data used by IGWA and IDWR for three WMIS records account for this 442 acre-feet difference.

Table 3: 2022 Reduction Comparison

1	2	3	4
Ground Water District	**IGWA Reported Reduction (AF)**	**IDWR Database Reduction (AF)**	**IDWR % Difference Compared to IGWA (negative = IDWR < IGWA)**
American Falls -Aberdeen GWD	14,493	13,003	-10.3
Bingham GWD	7,923	9,233	16.5
Bonneville - Jefferson GWD	6,888	4,296	-37.6
Carey Valley GWD	3,782	4,037	6.7
Henry's Fork GWD	8,724	6,560	-24.8
Jefferson - Clark GWD	37,281	36,836	-1.2
Madison GWD	1,176	3,195	171.7
Magic Valley GWD	37,429	37,840	1.1
North Snake GWD	33,957	28,831	-15.1
Total:	151,653	143,831	-5.2

Table 3 Notes:

- Data in this table are generated by subtracting the 2022 usage volume for each district in table 2 from the 5-year average baseline for each district in table 1.

Table 4: 2022 Recharge Contract Confirmation

Ground Water District	IGWA Volume (AF)	IDWR Volume (AF)
American Falls-Aberdeen	23,550	16,866
Bingham	516	516
Bonneville - Jefferson	9,285	9,285
Carey Valley	5	5
Hen. Fork & Madison	3,000	3,000
Jefferson Clark	7,647	7,647
Magic Valley	3,378	3,378
North Snake	3,568	3,567
Grand Total	50,948	44,264

Table 4 Notes:

- The difference of 6,684 acre-feet for American Falls-Aberdeen is specific to recharge activities under the City of Gooding permit number 37-23059. IDWR has requested additional information on this line item and is awaiting the response.
- The timeframe within which recharge activities are counted is the calendar year 2022.
- Recognizing the challenges and difficulties due to the current data gaps in regard to accurately knowing and measuring where, when and how much water was actually recharged, the Department limited its review to confirmation of private lease/rental contracts, temporary water permits, natural flow permits, water supply bank rentals and the contract volume amounts.

Respectfully,

Brian Ragan

Re: Assignment of 30,000 acre-feet to the Surface Water Coalition

Dear Tony:

By this letter, IGWA hereby assigns to the SWC 30,000 acre-feet of storage under the following lease contracts, copies of which are enclosed:

- 5,988 acre-feet under the Multi-Year Tribal Water Lease Agreement between IGWA and the Shoshone-Bannock Tribes.
- 4,000 acre-feet under the Storage Water Lease between Bonneville-Jefferson Ground Water District and Enterprize Canal Company.
- 4,000 acre-feet under the Storage Water Lease between Bonneville-Jefferson Ground Water District and Snake River Valley Irrigation District.
- 3,826 acre-feet under the Storage Water Lease lease between Bonneville-Jefferson Ground Water District and Idaho Irrigation District.
- 3,500 acre-feet under the Water District #1 Rental Pool – Private Lease Agreement between Bingham Ground Water District and Aberdeen-Springfield Canal Company.
- 5,009 acre-feet under the Water District #1 Rental Pool – Private Lease Agreement between Bingham Ground Water District and Snake River Valley Irrigation District.
- 400 acre-feet under the Water District #1 Rental Pool – Private Lease Agreement between Bingham Ground Water District and United Canal Company.
- 334 acre-feet under the Water District #1 Rental Pool – Private Lease Agreement between Bingham Ground Water District and Sunnydell Irrigation Company.
- 50 acre-feet under the Water District #1 Rental Pool – Private Lease Agreement between Bingham Ground Water District and Watson Canal Company.
- 150 acre-feet under the Water District #1 Rental Pool – Private Lease Agreement between Bingham Ground Water District and Wearyrick Ditch Company.
- 500 acre-feet under the Water District #1 Rental Pool – Private Lease Agreement between Bingham Ground Water District and Blackfoot Irrigation Company.
- 750 acre-feet under the Water District #1 Rental Pool – Private Lease Agreement between Bingham Ground Water District and Corbett Slough Ditch Company.

- 1,343 acre-feet under the Water District #1 Rental Pool – Private Lease Agreement between Bingham Ground Water District and Enterprize Canal Company.
- 100 acre-feet under the Water District #1 Rental Pool – Private Lease Agreement between Bingham Ground Water District and Parsons Ditch Company.
- 50 acre-feet under the Water District #1 Rental Pool – Private Lease Agreement between Bingham Ground Water District and Riverside Canal Company.

The Water District 1 fees associated with these leases have already been paid. Kent Fletcher, Travis Thompson, or another representative of the SWC will direct you as to which SWC storage accounts this water should be credited.

Thank you for your assistance. If you have any questions, please contact me.

Sincerely,

Thomas J. Budge

Re: Assignment of 50,000 acre-feet to the Surface Water Coalition

Dear Tony:

By this letter, IGWA hereby assigns to the SWC 50,000 acre-feet of storage under the following lease contracts, copies of which are enclosed:

- 19,000 acre-feet under the Multi-Year Tribal Water Lease Agreement between IGWA and the Shoshone-Bannock Tribes.
- 2,500 acre-feet under the One-Year Tribal Water Lease Agreement between IGWA and the Shoshone-Bannock Tribes.
- 2,514 acre-feet under the Water District #1 Rental Pool – Private Lease Agreement between Bingham Ground Water District and Peoples Canal & Irrigation Company.
- 327 acre-feet under the Water District #1 Rental Pool – Private Lease Agreement between Bingham Ground Water District and Enterprize Canal Company.
- 6,678 acre-feet under the Water District #1 Rental Pool – Private Lease Agreement between Bingham Ground Water District and Idaho Irrigation District.
- 5,009 acre-feet under the Water District #1 Rental Pool – Private Lease Agreement between Bingham Ground Water District and New Sweden Irrigation District.
- 1,000 acre-feet under the Storage Water Lease between American Falls-Aberdeen Ground Water District and Falls Irrigation District.
- 2,674 acre-feet under the Storage Water Lease between Bonneville-Jefferson Ground Water District and Idaho Irrigation District.[1]
- 5,000 acre-feet under the Water District #1 Rental Pool – Private Lease Agreement between Bingham Ground Water District and Harrison Canal and Irrigation Company.
- 2,270 acre-feet under the Water District #1 Rental Pool – Private Lease Agreement between Bingham Ground Water District and Peoples Canal & Irrigation Company.
- 500 acre-feet under the Water District #1 Rental Pool – Private Lease Agreement between Bingham Ground Water District and Blackfoot Irrigation Company.
- 50 acre-feet under the Water District #1 Rental Pool – Private Lease Agreement between Bingham Ground Water District and Wearyrick Ditch Company.

[1] 174 acre-feet under one Storage Water Lease between Bonneville-Jefferson Ground Water District and Idaho Irrigation District, dated April 21, 2023; 2,500 acre-feet under a second Storage Water Lease between the same, dated May 9, 2023.

- 1,500 acre-feet under the Water District #1 Rental Pool – Private Lease Agreement between Bingham Ground Water District and Corbett Slough Canal.
- 192 acre-feet under the Water District #1 Rental Pool – Private Lease Agreement between Bingham Ground Water District and Palisades Water Users, Inc.

The Water District 1 fees associated with these leases have already been paid. Kent Fletcher, Travis Thompson, or another representative of the SWC will direct you as to which SWC storage accounts this water should be credited.

Thank you for your assistance. If you have any questions, please contact me.

Sincerely,

Elisheva M. Patterson

Attorneys for the Cities of Bliss, Burley, Carey, Declo, Dietrich, Gooding, Hazelton, Heyburn, Jerome, Paul, Richfield, Rupert, Shoshone, and Wendell ("Coalition of Cities")

BEFORE THE DEPARTMENT OF WATER RESOURCES

OF THE STATE OF IDAHO

IN THE MATTER OF DISTRIBUTION OF WATER TO VARIOUS WATER RIGHTS HELD BY OR FOR THE BENEFIT OF A&B IRRIGATION DISTRICT, AMERICAN FALLS RESERVOIR DISTRICT #2, BURLEY IRRIGATION DISTRICT, MILNER IRRIGATION DISTRICT, MINIDOKA IRRIGATION DISTRICT, NORTH SIDE CANAL COMPANY, AND TWIN FALLS CANAL COMPANY	**Docket No. CM-DC-2010-001** **CITY OF POCATELLO'S, CITY OF IDAHO FALLS', AND COALITION OF CITIES' REQUEST FOR HEARING AND ORDER AUTHORIZING DISCOVERY**

COME NOW the City of Pocatello, City of Idaho Falls, and the Coalition of Cities[1] (collectively, the "Cities")[2], by and through their respective attorneys of record, and hereby request a hearing in the above-captioned matter and an order authorizing discovery.

[1] 1 The Coalition of Cities is composed of the Cities of Bliss, Burley, Carey, Declo, Dietrich, Gooding, Hazelton, Heyburn, Jerome, Paul, Richfield, Rupert, Shoshone, and Wendell.
[2] For purposes of economy, these requests are filed jointly, however, each party herein reserves the right to amend, supplement, or withdraw its requests individually without prejudice to the requests of another party to this filing.

A. Request for Hearing

Pursuant to Idaho Code § 42-1701(A)(3), the Cities request a hearing on the Idaho Department of Water Resource's ("Department") *Sixth Amended Methodology Order Regarding Methodology For Determining Material Injury to Reasonable In-Season Demand And Reasonable Carryover*, issued July 19, 2023 ("Sixth Methodology Order"). Among the issues the Cities have identified for hearing:

a) Whether the members of the Surface Water Coalition ("SWC") operate reasonably and without waste;

b) Whether the irrigated acreage numbers for the SWC members in the *Sixth Methodology Order* are accurate;

c) Whether the number of acres irrigated with supplemental groundwater rights within the service areas of the SWC members can be accurately determined;

d) Whether the number of acres irrigated with enlargement rights within the service areas of the SWC members can be accurately determined;

Because they need sufficient time to adequately conduct discovery and prepare for an evidentiary hearing, the Cities request that the Director set a four (4) day hearing pursuant to this request no sooner than September 1, 2024.

B. Request for Permission to Conduct Discovery

Pursuant to the Department's Procedure Rule 521, IDAPA 37.01.01.521, the Cities request that the Director issue an order authorizing discovery so that they can investigate

SWC members' operations and obtain the information and data necessary to properly litigate the issues listed above.

CONCLUSION

The Cities request that the Director (1) hold a status conference to set this matter for hearing; and (2) issue an order authorizing discovery.

Respectfully submitted this 3rd day of August 2023.

Attorneys for Idaho Ground Water Appropriators, Inc. (IGWA)

STATE OF IDAHO

DEPARTMENT OF WATER RESOURCES

IN THE MATTER OF DISTRIBUTION OF WATER TO VARIOUS WATER RIGHTS HELD BY OR FOR THE BENEFIT OF A&B IRRIGATION DISTRICT, AMERICAN FALLS RESERVOIR DISTRICT #2, BURLEY IRRIGATION DISTRICT, MILNER IRRIGATION DISTRICT, MINIDOKA IRRIGATION DISTRICT, NORTH SIDE CANAL COMPANY, AND TWIN FALLS CANAL COMPANY	Docket No. CM-DC-2010-001 **IGWA's Petition for Reconsideration**

Idaho Ground Water Appropriators, Inc. ("IGWA"), acting on behalf of North Snake Ground Water District, Carey Valley Ground Water District, Magic Valley Ground Water District, Aberdeen-American Falls Ground Water District, Jefferson-Clark Ground Water District, Madison Ground Water District, Henry's Fork Ground Water District, Bonneville-Jefferson Ground Water District, and Bingham Ground Water District, submits this petition for reconsideration of the *Notice that Questions Concerning the Sufficiency of IGWA's Mitigation Notices are Moot* ("*Notice*") issued July 20, 2023, by the Director of the Idaho Department of Water Resources ("Department").

Background

On April 21, 2023, the Director issued the *Fifth Amended Final Order Regarding Methodology for Determining Material Injury to Reasonable In-season Demand and Reasonable Carryover* ("*Fifth Methodology Order*"), and the *Final Order Regarding April 2023 Forecast Supply* ("*April 2023 As-Applied Order*"). The application of the two required IGWA to establish

that it could mitigate for its proportionate share of the predicted demand shortfall of 75,200 acre-feet in accordance with an approved mitigation plan, or else face curtailment. (*April 2023 As-Applied Order*, p. 6.)

On May 5, 2023, IGWA filed a *Notice of Ground Water District Mitigation* ("*Mitigation Notice*"). On May 23, 2023, the Director issued an *Order Determining Deficiency in IGWA's Notice of Secured Water* ("*Deficiency Order*"). The *Deficiency Order* concluded that: (1) some of IGWA's member ground water districts cannot mitigate under the 2009 Storage Water Plan while others mitigate under the 2015 Settlement Agreement Mitigation Plan; and (2) IGWA must tender fees to Water District 01 along with proof of legally enforceable contracts to demonstrate compliance with the 2009 Storage Water Mitigation Plan. (*Deficiency Order*, p. 5, 7.)

On June 1, 2023, IGWA filed *IGWA's Amended Notice of Mitigation* ("*Amended Mitigation Notice*") informing the Director that all IGWA districts would mitigate under the 2009 Storage Water Plan, and, while objecting to the new fee requirement, stated it had paid the Water District 01 fees. (*Amended Mitigation Notice*, p. 3.) On June 6, 2023, IGWA filed *IGWA's Petition for Reconsideration* formally objecting to the new requirement that Water District 01 fees be paid before the Director will accept signed storage water lease or option contracts as proof of IGWA's ability to provide storage water as mitigation.

On July 19, 2023, the Director issued the *Sixth Final Order Regarding Methodology for Determining Material Injury to Reasonable In-season Demand and Reasonable Carryover*, as well as an *Order Revising April 2023 Forecast Supply (Methodology Steps 5 & 6)* ("*July As-Applied Order*"). The *July As-Applied Order* found no demand shortfall was predicted for the Surface Water Coalition ("SWC"). (*July As-Applied Order*, p. 6.)

On July 20, 2023, the Director issued the *Notice that Questions Concerning the Sufficiency of IGWA's Mitigation Notices are Moot*, finding that because ground water users are no longer required to mitigate injury to the SWC, there is no longer a present justiciable controversy regarding IGWA's *Amended Mitigation Notice* or *IGWA's Petition for Reconsideration* related thereto. (*Notice*, p. 3.)

Argument

Generally, administrative bodies and courts refrain from issuing declaratory judgments where no live actual or justiciable controversy exists; however, there are important exceptions to this doctrine. A ruling on a moot issue may be made when: (1) "there is the possibility of collateral legal consequences imposed on the person raising the issue;" (2) "the challenged conduct is likely to evade judicial review and thus is capable of repetition;" and (3) "an otherwise moot issue raises concerns of substantial public interest." *Wylie v. State, Idaho Transp. Bd*., 151 Idaho 26, 31-32, 253 P.3d 700, 705-06 (2011); *Stephen v. Sallaz & Gatewood, Chtd*., 150 Idaho 521, 528, 248 P.3d 1256, 1263 (2011). Here, all three exceptions are met. This petition addresses exceptions 2 and 3 as they have the most obvious application.

A. The short period of time between issuance of the As-Applied Orders means challenges to the orders are likely to evade judicial review and repetition is all but assured.

Under the Methodology Orders, the Director is required to determine whether the SWC faces a demand shortfall during different times in the irrigation season. The Director makes these findings under a series of As-Applied Orders, the first of which is generally issued in April; the second, applying Steps 5 and 6 of the Methodology Order, in July; the third, applying Steps 7 and 8, in August; and, finally, the fourth, applying Step 9, in November. Under each of these As-Applied Orders, if a demand shortfall is predicted then junior ground water users must mitigate their proportionate share of the shortfall according to an approved mitigation plan.

Mitigation obligations may change with each As-Applied Order. For example, in 2023, the April As-Applied Order predicted a Demand Shortfall of 75,200 acre-feet, whereas the July As-Applied Order predicted no Demand Shortfall. This fluctuation in predicted Demand Shortfall, coupled with the short period of time between As-Applied Orders, means that issues concerning mitigation obligations by junior-priority groundwater users may evade judicial review. By the time an issue is raised under an April As-Applied Order, the July As-Applied Order has changed the conditions, potentially rendering the issue moot.

IGWA has a mitigation plan approved June 3, 2010, in IDWR Docket No. CM-MP-2009-007, which allows IGWA to provide mitigation by delivering storage water to the SWC. The order approving this plan allows IGWA to comply by providing "proof of rental or an option to rent storage water" evidenced by "fully executed and irrevocable contracts with holders of Snake River storage." (*Order Approving Mitigation Plan*, IDWR Docket No. CM-MP-2009-007, June 3, 2010.) Despite this, the Director's recent *Deficiency Order* requires, for the first time, that IGWA pay Water District 01 fees in addition to fully executed and irrevocable contracts with holders of Snake River storage.

If IGWA's objection to the new fee payment requirement is rendered moot every time a new As-Applied Order is issued, the objection is likely to evade review.

B. Compliance with As-Applied Orders is of substantial public interest because non-compliance could result in massive water right curtailments.

Common in the As-Applied Orders is the following statement: "If a junior ground water user cannot establish, to the satisfaction of the Director, that they can mitigate for their proportionate share of the predicted [Demand Shortfall] . . . in accordance with an approved mitigation plan, the Director will issue an order curtailing the junior-priority ground water user." (*April 2023 As-Applied Order*, p. 6.) IGWA's members irrigate almost one million acres of farmland, all of which are at risk of curtailment unless IGWA complies with an approved mitigation plan. Consequently, it is critical that IGWA understand what is required to demonstrate compliance with the 2009 Storage Water Mitigation Plan.

The Director's new fee payment requirement is very problematic because it may close the door to option contracts as a tool for securing storage water for mitigation purposes. The *Order Approving Mitigation Plan* issued in 2010 specifically authorizes option contracts as a tool to

demonstrate compliance. Under an option contract, IGWA does not hold an interest in the water until the option is exercised. Requiring IGWA to pay Water District 01 fees before IGWA exercises an option is problematic for obvious reasons. And further, is inconsistent with the *Order Approving Mitigation Plan*. If IGWA is no longer allowed to mitigate under option contracts, IGWA needs to know.

Moreover, requiring IGWA to pay Water District 01 fees in advance is unnecessary. IGWA has historically waited until July or August to pay Water District 01 fees on storage water that is provided to SWC as mitigation, and IGWA has never failed to pay such fees. A bar on option contracts may also have the unintended consequence of causing more harm to the SWC. If option contracts cannot be utilized by IGWA in the future, then that leaves IGWA fewer options to secure storage water and ensure the SWC receives the mitigation it needs.

Therefore, if the Director is adding new requirements to IGWA's approved mitigation plan, then the appropriate changes to the *Order Approving Mitigation Plan* must be made before the next As-Applied Order triggers a mitigation requirement. Given the large number of acres involved, and the magnitude of curtailment, it is of substantial public interest that this compliance issue be resolved.

CONCLUSION

For the foregoing reasons, IGWA respectfully requests the Director reconsider his *Notice that Questions Concerning the Sufficiency of IGWA's Mitigation Notices are Moot* and find that the 2009 Storage Water Mitigation Plan does not require payment of Water District 01 fees at the time of the notice of mitigation. This issue remains ripe for review because the issue is of substantial public interest and is likely to evade review.

Dated this 3rd day of August, 2023.

Attorneys for Idaho Ground Water Appropriators, Inc. (IGWA)

STATE OF IDAHO

DEPARTMENT OF WATER RESOURCES

IN THE MATTER OF DISTRIBUTION OF WATER TO VARIOUS WATER RIGHTS HELD BY OR FOR THE BENEFIT OF A&B IRRIGATION DISTRICT, AMERICAN FALLS RESERVOIR DISTRICT #2, BURLEY IRRIGATION DISTRICT, MILNER IRRIGATION DISTRICT, MINIDOKA IRRIGATION DISTRICT, NORTH SIDE CANAL COMPANY, AND TWIN FALLS CANAL COMPANY	Docket No. CM-DC-2010-001 Docket No. CM-DC-2016-001 **IGWA's Response to Surface Water Coalition's Petition for Reconsideration & Clarification and Request for Enforcement of Orders Approving 2016 Stipulated Plan**

Idaho Ground Water Appropriators, Inc. ("IGWA"), acting on behalf of North Snake Ground Water District, Carey Valley Ground Water District, Magic Valley Ground Water District, Aberdeen-American Falls Area Ground Water District, Jefferson-Clark Ground Water District, Madison Ground Water District, Henry's Fork Ground Water District, Bonneville-Jefferson Ground Water District, and Bingham Ground Water District, hereby responds to *Surface Water Coalition's Petition for Reconsideration & Clarification and Request for Enforcement of Orders Approving 2016 Stipulated Plan* ("SWC Petition") filed July 31, 2023, in IDWR Docket Nos. CM-DC-2010-001 and CM-MP-2016-001.

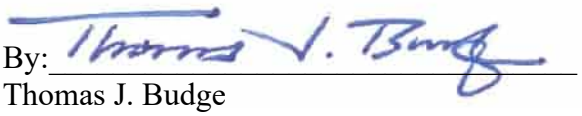
IGWA's Amended Notice of Mitigation filed June 1, 2023, states that IGWA will mitigate in 2023 in accordance with its "Storage Water Plan" approved in 2010 in IDWR Docket No. CM-MP-2009-007. Notwithstanding, the SWC asks the Director to rule that certain ground water districts are not in compliance in 2023 with IGWA's "Settlement Agreement Plan" approved in 2016 in IDWR Docket No. CM-MP-2016-001. The SWC argues that certain of IGWA's member ground water districts are "presumably not complying" with the Settlement Agreement Plan, and "there is no verification that IGWA is complying with its stipulated mitigation plan." (SWC

Petition, p. 4.) The premise of the SWC's argument is that even if IGWA complies with the approved Storage Water Plan, it is contractually obligated to also comply with the Settlement Agreement Plan. The Director should deny the SWC Petition for three reasons.

First, the SWC Petition is a collateral attack on issues that were raised in, and properly belong in, the SWC's challenge of the Director's *Final Order Regarding April 2023 Forecast Supply* ("April As-Applied Order") issued April 21, 2023. The April As-Applied Order states that junior priority groundwater users may mitigate "in accordance with an approved mitigation plan." (Emphasis added.) It does not obligate IGWA to mitigate under the Settlement Agreement Plan; it allows mitigation under any approved plan. This is consistent with Conjunctive Management Rule 30.07.g which requires the Director to "take into consideration the existence of any approved mitigation plan before issuing any order prohibiting or limiting withdrawal of water from any well," Conjunctive Management Rule 40.01.b which authorizes out-of-priority diversions "pursuant to a mitigation plan that has been approved by the Director," Conjunctive Management Rule 41.02.c which requires the Director to "consider the expected benefits of an approved mitigation plan," and Conjunctive Management Rule 42.02 which allows out-of-priority diversions if "the junior-priority right is covered by an approved and effectively operating mitigation plan."

The SWC requested a hearing on the April As-Applied Order and filed a statement of issues including: "Whether the order provides that IGWA has an option to comply with the mitigation plan approved in CM-MP-2016-001 to avoid curtailment by complying with the mitigation plan approved in CM-MP-2009-007 instead." (SWC Req. for Hrg. / Stmt. of Issues, May 5, 2023.) An evidentiary hearing was held June 6-9, 2023, post-hearing briefs were filed, and a decision was entered July 19, 2023. The SWC did not present any evidence at the hearing concerning the foregoing issue, and the Director did not change either the Methodology Order or the As-Applied Order to mandate that IGWA mitigate under the Settlement Agreement Plan. The SWC's attempt to raise that issue for a second time here is a collateral attack on the Director's *Post-Hearing Order Regarding Fifth Amended Methodology Order* issued July 19, 2023; therefore, it must be denied.

Second, even if the Director elects to address the SWC's mitigation plan argument, the Director has no legal basis for precluding IGWA from complying with any approved mitigation plan. The Storage Water Plan is an approved mitigation plan that has not been withdrawn or terminated. Nor do the terms of the Settlement Agreement Plan preclude IGWA from mitigating under the Storage Water Plan. If the SWC contends that IGWA has a contractual obligation to comply with the Settlement Agreement Plan irrespective of its compliance with the Storage Water Plan, the SWC must bring an action in district court for breach of contract. As to the Director's authority, it is limited to evaluating compliance with any approved mitigation plan.



Third, even if the Director were to rule that IGWA must comply with the Settlement Agreement Plan irrespective of its compliance with the Storage Water Plan, the SWC is not in a position to assert that IGWA is out of compliance. As noted in the SWC Petition, IGWA has delivered 50,000 acre-feet of storage to the SWC consistent with section 3.b.i of the IGWA-

SWC Settlement Agreement.[1] Any questions concerning IGWA's compliance with diversion reductions under section 3.a of the Agreement are not ripe for review until IGWA submits a performance report prior to April 1, 2024, in accordance with section 2.a.i of the Second Addendum to Settlement Agreement dated December 14, 2016.

For the foregoing reasons, IGWA respectfully requests that the Director deny the SWC Petition.

Dated this 3rd day of August, 2023.

RACINE OLSON, PLLP

By: 
Thomas J. Budge
Attorneys for IGWA

[1] Although IGWA elected to mitigate the April As-Applied Order demand shortfall under the Storage Water Plan, IGWA still delivered 50,000 acre-feet of storage water to the SWC, in a good faith effort to maintain the relationship. However, IGWA maintains that it may use the delivered 50,000 acre-feet of storage water to mitigate possible Methodology Order Step 7-8 demand shortfall, should injury be found later in the irrigation season. A letter from IGWA to the SWC, dated July 19, 2023, regarding the delivery of 50,000 acre-feet of storage water made this same reservation.

BEFORE THE DEPARTMENT OF WATER RESOURCES

OF THE STATE OF IDAHO

IN THE MATTER OF DISTRIBUTION OF WATER TO VARIOUS WATER RIGHTS HELD BY OR FOR THE BENEFIT OF A&B IRRIGATION DISTRICT, AMERICAN FALLS RESERVOIR DISTRICT #2, BURLEY IRRIGATION DISTRICT, MILNER IRRIGATION DISTRICT, MINIDOKA IRRIGATION DISTRICT, NORTH SIDE CANAL COMPANY, AND TWIN FALLS CANAL COMPANY	Docket No. CM-DC-2010-001 CM-MP-2016-001 **ORDER GRANTING PETITION FOR RECONSIDERATION/CLARIFICATION IN PART AND DENYING REQUEST FOR ENFORCEMENT**

BACKGROUND

On July 19, 2023, the Director of the Idaho Department of Water Resources ("Department") issued his *Sixth Final Order Regarding Methodology for Determining Material Injury to Reasonable In-Season Demand and Reasonable Carryover* ("Sixth Methodology Order") and *Order Revising April 2023 Forecast Supply and Amending Curtailment Order (Methodology Steps 5 & 6)* ("April 2023 As-Applied Order"). The Sixth Methodology Order comprises nine steps to determine material injury to members of the Surface Water Coalition ("SWC"). The April 2023 As-Applied Order applies Steps 5 and 6 to the 2023 irrigation season.

On July 20, 2023, the Director issued his *Notice that Questions Concerning the Sufficiency of IGWA's Mitigation Notices are Moot* ("Notice"). The Notice concluded that questions concerning the sufficiency of IGWA's mitigation notices are moot. Because of mootness, the Department did not respond to *IGWA's Petition for Reconsideration of Order Determining Deficiency in IGWA's Notice of Secured Water*, filed June 6, 2023, or *IGWA's Amended Notice of Mitigation*, filed June 1, 2023.

The Department received the *Surface Water Coalition's Petition for Reconsideration and Clarification; Request for Enforcement of Orders Approving 2016 Stipulated Plan* ("SWC's Petition") on July 31, 2023. The SWC's Petition requests the Director reconsider and clarify a statement made in the April 2023 As-Applied Order— "there is no need to establish a Time of Need as described in Step 6"—and a statement made in the Notice— "[b]ecause there is no demand shortfall, ground water users are no longer required to mitigate." *SWC's Petition* at 3. Additionally, the SWC's Petition requests the Director address IGWA's 2022 breach through enforcement of the orders approving the March 9, 2016 *Stipulated Mitigation Plan and Request for Order* and its amendments. *Id*. at 3, 5.

On August 3, 2023, the Idaho Ground Water Appropriators, Inc. ("IGWA") filed with the Department *IGWA's Response to Surface Water Coalition's Petition for Reconsideration and Clarification and Request for Enforcement of Orders Approving 2016 Stipulated Plan*.

ANALYSIS

A. April 2023 As-Applied Order

The April 2023 As-Applied Order states "[w]ith no additional water owed to SWC members, there is no need to establish a Time of Need as described in Step 6." *April 2023 As-Applied Order* at 8.

The SWC asks the Director to "reconsider or clarify this statement to provide the parties with notice that this statement is not definitive for the rest of the 2023 irrigation season, and that additional adjustments may be made depending upon climatic conditions and available water supplies." *SWC's Petition* at 5.

The Director will clarify this statement. This statement is not definitive for the rest of the 2023 irrigation season. "The Time of Need is established by predicting the day in which the remaining storage allocation will be equal to reasonable carryover." *Sixth Methodology Order* at 21. Because there was no shortfall calculated in the April 2023 As-Applied Order, it was not necessary to predict the Time of Need in that order. However, the Department is tracking the Time of Need and will issue an order prior to the Time of Need as described in Step 7 of the Methodology Order.[1]

B. Notice

The Notice states "[b]ecause there is no demand shortfall, ground water users are no longer required to mitigate." *Notice* at 3.

The SWC asks the Director to "reconsider or clarify the statement that 'ground water users are no longer required to mitigate,' particularly to the extent that statement may be interpreted to obviate any requirements" under an approved mitigation plan. *SWC's Petition* at 4.

The Director will clarify this statement. The statement was not intended to suggest that ground water users seeking protection of an approved mitigation plan do not need to continue to comply with the obligations described in the mitigation plan.

C. Request for Enforcement

The SWC states "[g]iven the April impasse of the Steering Committee, and IDWR's recent verification of IGWA's failure to perform as required in 2022, the [SWC] requests the Director to enforce the orders approving the *Stipulated Plan* and its amendments." *SWC's Petition* at 5.

---

[1] Step 7 states "Shortly before the estimated Time of Need, but following the events described in Steps 5 and 6, the Director will, for each member of the SWC: (1) recalculate RISD; (2) issue a revised FS; and (3) establish the Time of Need." *Sixth Methodology Order* at 44.

On August 3, 2023, after the SWC's request was filed, the Director issue his *Final Order Regarding IGWA's 2022 Mitigation Plan Compliance* related to IGWA's breach in 2022 of the mitigation plan approved in 2016 in Docket No. CM-MP-2016-001. Issues related to IGWA's compliance with the mitigation plan should be addressed in proceedings related to that order.

ORDER

Based upon and consistent with the foregoing, IT IS HEREBY ORDERED as follows:

The Director GRANTS IN PART the SWC's petition for reconsideration/clarification.

The Director DENIES the SWC's request for enforcement as the Director recently issued his *Final Order Regarding IGWA's 2022 Mitigation Plan Compliance*.

DATED this 11th day of August 2023.

GARY SPACKMAN
Director

CERTIFICATE OF SERVICE

I HEREBY CERTIFY that on this 11th day of August 2023, the above and foregoing, was served by the method indicated below, and addressed to the following:

EXPLANATORY INFORMATION TO ACCOMPANY A FINAL ORDER

(To be used in connection with actions when a hearing was **not** held)

(Required by Rule of Procedure 740.02)

The accompanying order is a "**Final Order**" issued by the department pursuant to section 67-5246, Idaho Code.

PETITION FOR RECONSIDERATION

Any party may file a petition for reconsideration of a final order within fourteen (14) days of the service date of this order as shown on the certificate of service. **Note: The petition must be received by the Department within this fourteen (14) day period.** The department will act on a petition for reconsideration within twenty-one (21) days of its receipt, or the petition will be considered denied by operation of law. See section 67-5246(4), Idaho Code.

REQUEST FOR HEARING

Unless the right to a hearing before the director or the water resource board is otherwise provided by statute, any person who is aggrieved by the action of the director, and who has not previously been afforded an opportunity for a hearing on the matter shall be entitled to a hearing before the director to contest the action. The person shall file with the director, within fifteen (15) days after receipt of written notice of the action issued by the director, or receipt of actual notice, a written petition stating the grounds for contesting the action by the director and requesting a hearing. See section 42-1701A(3), Idaho Code. **Note: The request must be received by the Department within this fifteen (15) day period.**

APPEAL OF FINAL ORDER TO DISTRICT COURT

Pursuant to sections 67-5270 and 67-5272, Idaho Code, any party aggrieved by a final order or orders previously issued in a matter before the department may appeal the final order and all previously issued orders in the matter to district court by filing a petition in the district court of the county in which:

i. A hearing was held,
ii. The final agency action was taken,
iii. The party seeking review of the order resides, or
iv. The real property or personal property that was the subject of the agency action is located.

The appeal must be filed within twenty-eight (28) days of: a) the service date of the final order, b) the service date of an order denying petition for reconsideration, or c) the failure within twenty-one (21) days to grant or deny a petition for reconsideration, whichever is later. See section 67-5273, Idaho Code. The filing of an appeal to district court does not in itself stay the effectiveness or enforcement of the order under appeal.

Attorneys for American Falls Reservoir District #2 and Minidoka Irrigation District

BEFORE THE DEPARTMENT OF WATER RESOUCES

OF THE STATE OF IDAHO

IN THE MATTER OF DISTRIBUTION OF WATER TO VARIOUS WATER RIGHTS HELD BY OR FOR THE BENEFIT OF A&B IRRIGATION DISTRICT, AMERICAN FALLS RESERVOIR DISTRICT #2, BURLEY IRRIGATION DISTRICT, MILNER IRRIGATION DISTRICT, MINIDOKA IRRIGATION DISTRICT, NORTH SIDE CANAL COMPANY, AND TWIN FALLS CANAL COMPANY	Docket No. CM-DC-2010-001 **SURFACE WATER COALITION'S RESPONSE TO CITIES' REQUEST FOR HEARING AND ORDER AUTHORIZING DISCOVERY**

COME NOW, A&B IRRIGATION DISTRICT, AMERICAN FALLS RESERVOIR DISTRICT #2, BURLEY IRRIGATION DISTRICT, MILNER IRRIGATION DISTRICT, MINIDOKA IRRIGATION DISTRICT, NORTH SIDE CANAL COMPANY, and TWIN FALLS CANAL COMPANY ("Surface Water Coalition" or "Coalition"), by and through counsel of record, and hereby respond to the *City of Pocatello's, City of Idaho Falls', and Coalition of Cities' Request for Hearing and Order Authorizing Discovery* ("Request") filed on August 3,

2023. The Coalition requests the Director to deny the Cities' Request for the reasons set forth below.

BACKGROUND

The Director issued the *Fifth Amended Methodology Order Regarding Methodology for Determining Material Injury to Reasonable In-Season Demand and Reasonable Carryover* ("Fifth Methodology Order") on April 21, 2023. The Cities challenged that order and filed several requests for hearing. *See Pocatello's Request for Hearing* (April 28, 2023); *Coalition of Cities' Amended Request for Hearing* (April 28, 2023); *City of Idaho Falls Challenge and Request for Hearing* (May 4, 2023). The Cities later filed additional statements of issues. *See Pocatello's Statement of Issues* (May 4, 2023); *Coalition of Cities' Statement of Issues* (May 4, 2023); *City of Idaho Falls Statement of Issues* (May 4, 2023). Notably, the Cities raised the following issues subject to the administrative hearing that was held from June 6-9, 2023:

> c) Whether the Surface Water Coalition's ("SWC") actual irrigated acreage was properly determined for use in determining reasonable in-season demand; . . .
>
> e) The reasonableness of Project efficiencies of the SWC members, trends in said efficiencies in recent years, and how the efficiency values are used in determining reasonable in-season demands;
>
> f) IDWR's failure to consider all sources of supply to the SWC;

Pocatello's Request for Hearing at 2; *see also Pocatello's Statement of Issues* at 2.

> b) IDWR's failure to properly identify the Surface Water Coalition's ("SWC") irrigated acreage used in the determination of reasonable in-season demand; . . .
>
> d) IDWR's failure to consider changes in the efficiency of the SWC's operations;
>
> e) IDWR's failure to consider all sources of supply available to the SWC;

Coalition of Cities' Amended Request for Hearing at 2.

> 4. IDWR's failure to consider changes and reasonableness of the project efficiencies of the SWC's operations; . . .

> 11. IDWR's failure to investigate whether the SWC members are using the water they divert efficiently and without waste, and in compliance with the terms of their decreed water rights;

Coalition of Cities' Statement of Issues at 2-3.

> 4. The reasonableness of Project efficiencies of the SWC members, trends in the efficiencies in recent years, and how the efficiency values are used in determining reasonable in-season demands;
>
> 5. Whether IDWR failed to consider all sources of water supply to the SWC; . . .
>
> 12. Whether IDWR's failure to investigate whether the SWC members are using the water they divert efficiently and without waste, and in compliance with the terms of their decreed water rights;

City of Idaho Falls Statement of Issues at 2-3.

The parties were allowed to address the above issues at hearing through both lay and expert testimony and through exhibits.[1] The parties also submitted post-hearing briefing on all issues that were raised, or could have been raised, at the hearing. *See generally, Cities' Closing Brief* (June 16, 2023). The Director issued the *Post-Hearing Order Regarding Fifth Amended Methodology Order* and the *Sixth Final Order Regarding Methodology for Determining Material Injury to Reasonable In-season Demand and Reasonable Carryover* ("Sixth Methodology Order") on July 19, 2023.

The Sixth Methodology Order was issued as a "final" administrative order subject to reconsideration and/or appeal to district court. *See* I.C. §§ 67-5246; 67-5270 to 5272; *see also*, Explanatory Information to Accompany a Final Order (attached to the Director's Sixth Methodology Order).

[1] These issues are essentially the same issues identified in the Cities' present Request. *See Request* at 2 (i.e. "operate reasonably and without waste," "irrigated acreage," "supplemental groundwater" and "enlargement rights"). All of these issues address the Coalitions' use of water and the Cities had an opportunity to discover and present this information at the June hearing.

ARGUMENT

I. IDWR Already Provided a Hearing on the Cities' Issues and the Statute Does Not Provide for a Second Hearing.

The Cities have erroneously petitioned for an administrative hearing on the Sixth Methodology Order pursuant to Idaho Code § 42-1701A(3). The statute only allows an aggrieved person to have a hearing on a director's action or order when that person "has not previously been afforded an opportunity for hearing on the matter." *See* I.C. § 42-1701A(3). The Cities do not fall into that category. Instead, IDWR provided the Cities with an opportunity for hearing on the issues listed in their recent *Request for Hearing* June 6-9, 2023. Issues related to the SWC's reasonable use of water, irrigated acres, supplemental groundwater, and enlargement rights were all subject to the hearing on the Fifth Amended Methodology Order held before the Director this past June. The Director specifically addressed these issues in the Post-Hearing Order. *See Post-Hearing Order* at 17-23. Although the Cities may disagree with the Director's decision, their remedy is not a "second" administrative hearing. Since the Cities had an opportunity for a hearing on their issues, Idaho law does not afford them a right to a "second" hearing. The Cities' request should be denied accordingly.

Moreover, the Sixth Methodology Order was issued as a "final" agency order. Pursuant to section 42-1701A(4) the Cities' statutory remedy is judicial review of that order. Idaho's APA provides the right to ask for reconsideration and/or appeal that decision to district court. The Cities did not ask for reconsideration and have yet to appeal the Sixth Methodology Order, however IGWA did ask for judicial review. *See IGWA's Petition for Judicial Review* (Ada County Dist. Ct., Fourth Jud. Dist., Case No. CV01-23-13713, Aug. 16, 2023). Since the Director's Sixth Methodology Order is on appeal to the district court it is not subject to any

further administrative process or hearing, unless ordered by the court. *See* I.R.C.P. 84. The Cities' request for a "second" hearing should be denied accordingly.

II. The Sixth Methodology Order Updates the Fifth Methodology Order Based on Information Produced at Hearing.

Notwithstanding the Sixth Methodology Order was issued as a "final" agency order subject to reconsideration and/or judicial review, the Director updated the Fifth Order based upon information produced at hearing. In other words, the issues that the Cities seek to address with a hearing on the Sixth Methodology Order were already addressed in the June hearing. There is nothing new in the final order that would warrant an additional administrative hearing. The Cities' request in this regard is unduly burdensome and would cost the parties and agency time and additional resources without any legal basis.

Notably, the Director stated "[t]his Sixth Methodology Order relies on the same data included in the Fifth Methodology Order." *See* Sixth Methodology Order at 8, n. 8, at 9, n. 9, at 10, n .10, at 15, n. 13, at 24, n. 18, at 26, n. 20, at 28-29, n. 21 (emphasis added). All of this information was available to the Cities as of April 21, 2023. However, the Director did identify certain limited corrections to the Fifth Methodology Order:

> As discussed in footnote 12, during the June 2023 Hearing the Department identified an error in AFRD's 2018 diversion data. Hr'g T. vol. IV, at 173-74. This correction was resolved in his Sixth Methodology Order, which relies on the updated data. The updated data did not result in an appreciable increase in 2018's diversion value.

Sixth Methodology Order at 12, n. 11.

> In this Sixth Methodology Order, AFRD2's 2018 diversion value has been increased by 5,000 acre-feet. This increase was necessary to remedy the error committed by Department staff in calculating AFRD2's 2018 adjusted diversion value for the Fifth Methodology Order, which was identified during the June 6 Hearing.

Id. at 13, n. 12.

IDWR staff member Matt Anders addressed the above data correction during the June hearing. He was available for cross-examination by the parties and the Cities had a full and fair opportunity to rebut or contest this information if they disagreed with it. Moreover, the Cities had a full and fair opportunity to rebut and contest any of IDWR's updates to the Fifth Methodology Order that were carried over to the Sixth Methodology Order. Stated another way, there is nothing new in the recent order that was not subject to the June hearing on the Fifth Methodology Order. All of the Cities' issues identified in their *Request for Hearing* were either expressly raised or could have been raised at the June hearing and finally addressed in the Director's *Post-Hearing Order* which resulted in the final Sixth Methodology Order.[2]

Alternatively, and without waiving any right to contest the granting of such a hearing, if the Director grants the Cities' request then the hearing should be limited to the issue of the updated data regarding AFRD2's 2018 diversion volume. The Director has such discretion and has limited review of amended methodology orders in that fashion before. This is the only change in the Sixth Methodology Order that could even be considered subject to another hearing. *See Order Limiting Scope of Evidence and Offering Witnesses (Methodology Order)* (May 21, 2010).

Similar to the request for hearing, the Director should deny or limit the Cities' request for discovery. Any issues that were already addressed at the hearing on the Fifth Methodology Order would be beyond the scope of discovery regarding a hearing on the additional data regarding AFRD2's 2018 diversion volume. Moreover, the Cities' request would be unduly

[2] The Cities have requested judicial review of the July 19, 2023 *Post-Hearing Order*. *See Notice of Appeal and Petition for Judicial Review* (Ada County Dist. Ct., Fourth Jud. Dist., Case No. CV01-23-13238, Aug. 16, 2023). It is anticipated that this appeal will be consolidated with IGWA's appeal of the Sixth Order.

repetitious and burdensome to the SWC in both time and expense. The Director should deny or limit the request accordingly.

CONCLUSION

The Cities' request for hearing on the Sixth Methodology Order is an impermissible attempt at a "second" hearing not authorized by statute. Moreover, Idaho law does not allow an agency to hold a "redo" administrative hearing of a final agency order that is pending on appeal to the district court. Since the Cities' issues were already addressed at the underlying hearing held in June, there is no basis to grant a second hearing on the Sixth Methodology Order.

The Coalition respectfully requests the Director to deny or limit the Cities' request for hearing and an order authorizing discovery accordingly.

Jessica Nielsen
Assistant for Travis L. Thompson

BEFORE THE DEPARTMENT OF WATER RESOURCES

OF THE STATE OF IDAHO

IN THE MATTER OF DISTRIBUTION OF WATER TO VARIOUS WATER RIGHTS HELD BY OR FOR THE BENEFIT OF A&B IRRIGATION DISTRICT, AMERICAN FALLS RESERVOIR DISTRICT #2, BURLEY IRRIGATION DISTRICT, MILNER IRRIGATION DISTRICT, MINIDOKA IRRIGATION DISTRICT, NORTH SIDE CANAL COMPANY, AND TWIN FALLS CANAL COMPANY	Docket No. CM-DC-2010-001 **ORDER DENYING IGWA'S PETITION FOR REVIEW**

BACKGROUND

On July 20, 2023, the Director issued his *Notice that Questions Concerning the Sufficiency of IGWA's Mitigation Notices are Moot* ("Notice"). The Notice concluded that questions concerning the sufficiency of IGWA's mitigation notices are moot, therefore, the Department would not respond to *IGWA's Petition for Reconsideration of Order Determining Deficiency in IGWA's Notice of Secured Water*, filed June 6, 2023, or *IGWA's Amended Notice of Mitigation*, filed June 1, 2023.

On August 3, 2023, the Department received *IGWA's Petition for Reconsideration* ("Petition"). The Petition seeks reconsideration of the Department's Notice, specifically, it asks the Department to "find that the 2009 Storage Water Mitigation Plan does not require payment of Water District 01 fees at the time of the notice of mitigation." *Petition* at 4.

ANALYSIS

The Department's Notice was not issued as a recommended, preliminary, or final order, as defined in the Department's Rules of Procedure 720, 730, or 740, IDAPA 37.01.01. Therefore, the Notice is not subject to a petition for reconsideration. The Department will treat IGWA's Petition as a petition to review an interlocutory order, in accordance with IDAPA 37.01.01.711.[1]

IGWA argues that exceptions to the mootness doctrine apply to the Water District 01 fees question and asks the Director to address the Water District 01 fees now. *Petition* at 4. IGWA argues that

> A ruling on a moot issue may be made when: (1) "there is the possibility of collateral legal consequences imposed on the person raising the issue;" (2) "the challenged conduct is likely to evade judicial review and thus is capable of

[1] IDAPA 37.01.01.711 states in part: "[a]ny party or person affected by an interlocutory order may petition the presiding officer to review the interlocutory order."

repetition;" and (3) "an otherwise moot issue raises concerns of substantial public interest." *Wylie v. State, Idaho Transp. Bd.*, 151 Idaho 26, 31-32, 253 P.3d 700, 705-06 (2011); *Stephen v. Sallaz & Gatewood, Chtd.*, 150 Idaho 521, 528, 248 P.3d 1256, 1263 (2011). Here, all three exceptions are met. This petition addresses exceptions 2 and 3 as they have the most obvious application.

Id. at 2.

The Director disagrees that the issue is likely to evade judicial review in the future. IGWA argues that its "objection to the new fee payment requirement is rendered moot every time a new As-Applied Order is issued." *Id*. at 3. This is not correct. In this season, the issue was rendered moot because a mid-season order determined that there was no longer an obligation. There is no guarantee that future mid-season orders will result in a determination that there is no longer an obligation. Thus, the issue is not likely to evade judicial review.

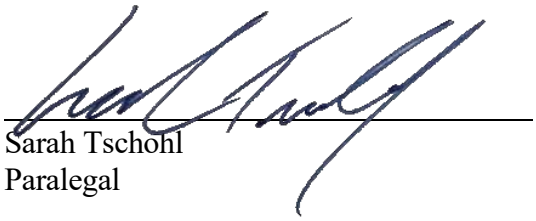
With regards to the substantial public interest exception, the Director declines to exercise this exception because there is no substantial interest in having the issue decided now. The subject matter is not likely to evade judicial review and a presiding officer can decline to exercise this exception where the matter will not escape judicial review. *See Freeman v. Idaho Dep't of Correction*, 138 Idaho 872, 877, 71 P.3d 471, 476 (Ct. App. 2003) ("Further, even if Freeman's allegation of constitutional violations involving inmates' meaningful court access issue were deemed to be of substantial public interest, the number of such claims that reach the courts render it unlikely that recurrences of denied meaningful court access will escape judicial review.")

ORDER

IT IS HEREBY ORDERED that the Director DENIES *IGWA's Petition for Reconsideration*.

DATED this 23rd day of August 2023.

GARY SPACKMAN
Director



CERTIFICATE OF SERVICE

BEFORE THE DEPARTMENT OF WATER RESOURCES

OF THE STATE OF IDAHO

IN THE MATTER OF DISTRIBUTION OF WATER TO VARIOUS WATER RIGHTS HELD BY OR FOR THE BENEFIT OF A&B IRRIGATION DISTRICT, AMERICAN FALLS RESERVOIR DISTRICT #2, BURLEY IRRIGATION DISTRICT, MILNER IRRIGATION DISTRICT, MINIDOKA IRRIGATION DISTRICT, NORTH SIDE CANAL COMPANY, AND TWIN FALLS CANAL COMPANY	Docket No. CM-DC-2010-001 **ORDER DENYING REQUEST FOR HEARING AND MOTION AUTHORIZING DISCOVERY**

BACKGROUND

On June 6–9, 2023 a hearing was held on the Department's April 21, 2023 *Fifth Amended Final Order Regarding Methodology for Determining Material Injury to Reasonable In-Season Demand and Reasonable Carryover* ("Fifth Methodology Order"). On July 19, 2023, the Director of the Idaho Department of Water Resources ("Department") issued his *Post-Hearing Order Regarding Fifth Amended Methodology Order* ("Post-Hearing Order") and *Sixth Final Order Regarding Methodology for Determining Material Injury to Reasonable In-Season Demand and Reasonable Carryover* ("Sixth Methodology Order"). The Sixth Methodology Order corrects data in the Department's Fifth Methodology Order found to be in error during the hearing held in this matter. The Sixth Methodology Order, like the Fifth Methodology Order, comprises nine steps to determine material injury to members of the Surface Water Coalition ("SWC").

On August 3, 2023, the Department received the *City of Pocatello's, City of Idaho Falls', and Coalition of Cities' Request for Hearing and Order Authorizing Discovery* ("Request for Hearing and Discovery"). The Request for Hearing and Discovery asks the Director to hold a status conference to schedule a four-day hearing, pursuant to Idaho Code § 42-1701(A)(3), on the Sixth Methodology Order and for an order authorizing discovery, pursuant to IDAPA 37.01.01.521. *Request for Hearing and Discovery* at 2–3. Four issues for hearing are identified in the Request for Hearing and Discovery:

> a) Whether the members of the Surface Water Coalition ("SWC") operate reasonably and without waste;
>
> b) Whether the irrigated acreage numbers for the SWC members in the Sixth Methodology Order are accurate;
>
> c) Whether the number of acres irrigated with supplemental groundwater rights within the service areas of the SWC members can be accurately determined; [and]

d) Whether the number of acres irrigated with enlargement rights within the service areas of the SWC members can be accurately determined[.]

Id. at 2.

On August 22, 2023, the Department received the *Surface Water Coalition's Response to Cities' Request for Hearing and Order Authorizing Discovery* ("SWC's Response"). The SWC's Response requests the Director "deny or limit the Cities' request for hearing and an order authorizing discovery . . . ." *SWC's Response* at 7.

ANALYSIS AND CONCLUSIONS OF LAW

A. Request for hearing.

Idaho Code § 42-1701A(3) states in relevant part:

> Unless the right to a hearing before the director . . . is otherwise provided in by statute, any person aggrieved by any action of the director, including any decision, determination, order or other action . . . who is aggrieved by the action of the director, and who has not previously been afforded an opportunity for a hearing on the matter shall be entitled to a hearing before the director to contest the action.

I.C. § 42-1701A(3) (emphasis added). The parties have previously been afforded an opportunity for hearing on the issues identified related to the Sixth Methodology Order and are not entitled to a hearing pursuant to Idaho Code § 42-1701A(3).

Over the course of four days, the Director heard testimony regarding the Fifth Methodology Order, including testimony on the reasonableness of the SWC's efficiency and waste and the accuracy of the irrigated acreage numbers utilized. "Testimony at the hearing established that the SWC entities operated efficiently within the limits of their delivery system." *Post-Hearing Order* at 23. "The ground water users did not establish an alternative number of acres irrigated by clear and convincing evidence." *Id*. at 19. "The record in this matter . . . lacks sufficient evidence to justify a reduction of the total number of acres irrigated with surface water by SWC members." *Id*.

A hearing on the Fifth Methodology Order was held less than one month before the Request for Hearing and Discovery was filed. The Sixth Methodology Order was issued as a direct result of the hearing. While methodology orders in this matter are subject to review and revision as conditions and the best available science change, *see In Matter of Distribution of Water to Various Water Rts. Held By or For Ben. of A & B Irrigation Dist.*, 155 Idaho 640, 653, 315 P.3d 828, 841 (2013), that review cannot reasonably be interpreted to equate to a right to a revolving door of administrative hearings. The Director therefore denies the request for hearing.[1]

[1] The Director emphasizes that this denial does not prevent the ground water users from presenting updated scientific information or data to the Director in the future. For example, if the ground water users prepare a new

B. Motion to Authorize Discovery.

The Request for Hearing and Discovery requests "an order authorizing discovery so that they can investigate SWC members' operations and obtain the information and data necessary to properly litigate the issues listed above." *Request for Hearing and Discovery* at 2–3. Because the Director is denying the request for hearing, the request to authorize discovery is moot. The Director therefore denies the request for discovery.

ORDER

IT IS HEREBY ORDERED that the *City of Pocatello's, City of Idaho Falls', and Coalition of Cities' Request for Hearing and Order Authorizing Discovery* is DENIED.

DATED this 23rd day of August 2023.

GARY SPACKMAN
Director

analysis of hardened acres within the boundary of a SWC member, this would be new information the Director may consider in the future.

EXPLANATORY INFORMATION TO ACCOMPANY A FINAL ORDER

(To be used in connection with actions when a hearing was **not** held)

(Required by Rule of Procedure 740.02)

The accompanying order is a "**Final Order**" issued by the department pursuant to section 67-5246, Idaho Code.

PETITION FOR RECONSIDERATION

Any party may file a petition for reconsideration of a final order within fourteen (14) days of the service date of this order as shown on the certificate of service. **Note: The petition must be received by the Department within this fourteen (14) day period.** The department will act on a petition for reconsideration within twenty-one (21) days of its receipt, or the petition will be considered denied by operation of law. See section 67-5246(4), Idaho Code.

REQUEST FOR HEARING

Unless the right to a hearing before the director or the water resource board is otherwise provided by statute, any person who is aggrieved by the action of the director, and who has not previously been afforded an opportunity for a hearing on the matter shall be entitled to a hearing before the director to contest the action. The person shall file with the director, within fifteen (15) days after receipt of written notice of the action issued by the director, or receipt of actual notice, a written petition stating the grounds for contesting the action by the director and requesting a hearing. See section 42-1701A(3), Idaho Code. **Note: The request must be received by the Department within this fifteen (15) day period.**

APPEAL OF FINAL ORDER TO DISTRICT COURT

Pursuant to sections 67-5270 and 67-5272, Idaho Code, any party aggrieved by a final order or orders previously issued in a matter before the department may appeal the final order and all previously issued orders in the matter to district court by filing a petition in the district court of the county in which:

i. A hearing was held,
ii. The final agency action was taken,
iii. The party seeking review of the order resides, or
iv. The real property or personal property that was the subject of the agency action is located.

The appeal must be filed within twenty-eight (28) days of: a) the service date of the final order, b) the service date of an order denying petition for reconsideration, or c) the failure within twenty-one (21) days to grant or deny a petition for reconsideration, whichever is later. See section 67-5273, Idaho Code. The filing of an appeal to district court does not in itself stay the effectiveness or enforcement of the order under appeal.

Revised July 1, 2010

BEFORE THE DEPARTMENT OF WATER RESOURCES

OF THE STATE OF IDAHO

IN THE MATTER OF DISTRIBUTION OF WATER TO VARIOUS WATER RIGHTS HELD BY OR FOR THE BENEFIT OF A&B IRRIGATION DISTRICT, AMERICAN FALLS RESERVOIR DISTRICT #2, BURLEY IRRIGATION DISTRICT, MILNER IRRIGATION DISTRICT, MINIDOKA IRRIGATION DISTRICT, NORTH SIDE CANAL COMPANY, AND TWIN FALLS CANAL COMPANY	Docket No. CM-DC-2010-001 **FINAL ORDER CURTAILING GROUND WATER RIGHTS JUNIOR TO OCTOBER 11, 1900**

The Director of the Idaho Department of Water Resources ("Department") finds, concludes, and orders as follows:

FINDINGS OF FACT

1. On July 19, 2023, the Director issued the *Sixth Final Order Regarding Methodology for Determining Material Injury to Reasonable In-Season Demand and Reasonable Carryover* ("*Methodology Order*").[1] The *Methodology Order* established nine steps for determining material injury to members of the Surface Water Coalition ("SWC").[2]

2. On April 16, 2025, the Director issued his *Final Order Regarding April 2025 Forecast Supply (Methodology Steps 1–3)* ("*April Forecast Supply Order*"). The *April Forecast Supply Order* predicted an in-season demand shortfall ("IDS") to the SWC of 63,000 acre-feet for the 2025 irrigation season. *April Forecast Supply Order*, at 3. At that time, the only member of the SWC predicted to experience material injury during the 2025 irrigation season was Twin Falls Canal Company ("TFCC"). *Id* at 3–4.

3. As a result, the Director ordered that:

> On or before May 1, 2025, ground water users holding consumptive water rights bearing priority dates junior to August 28, 1955, within the Eastern Snake Plain Aquifer area of common ground water supply [("ESPA ACGWS")] shall establish, to the satisfaction of the Director, that they can mitigate for their proportionate

[1] Shortly after the *Methodology Order* was issued, the Idaho Ground Water Appropriators, Inc. ("IGWA") and certain Idaho cities filed petitions for judicial review in Ada County (Nos. CV01-23-13173 and CV01-23-13238). IGWA's petition for judicial review is stayed until December 31, 2027. The cities' petition for judicial review is pending before the Idaho Supreme Court. The filing of a petition for judicial review does not stay the effectiveness of an order. I.C. § 67-5274. No party to the judicial review proceedings has requested a stay of the *Methodology Order*.

[2] The SWC is comprised of A&B Irrigation District, American Falls Reservoir District #2, Burley Irrigation District, Milner Irrigation District, Minidoka Irrigation District, North Side Canal Company, and Twin Falls Canal Company.

> share of the predicted April IDS of 63,000 acre-feet in accordance with an approved mitigation plan. If a junior ground water user cannot establish, to the satisfaction of the Director, that they can mitigate for their proportionate share of the predicted April IDS in accordance with an approved mitigation plan, the Director will issue an order curtailing the junior-priority ground water user.

April Forecast Supply Order, at 6.

4. On May 16, 2025, the Director issued a *Final Order Curtailing Ground Water Rights Junior to August 28, 1955* ("*Curtailment Order*"). The Director ordered that:

> [E]ffective May 31, 2025, ground water users holding water rights bearing priority dates junior to August 28, 1955, within the ESPA ACGWS, and listed in Attachment A to this order, shall curtail/refrain from diversion and use of ground water pursuant to those water rights unless notified by the Department that the order of curtailment has been modified or rescinded as to their water rights.

Curtailment Order, at 4.

5. On July 10, 2025, the Director issued the *Order Revising April 2025 Forecast Supply and Continuing May 16, 2025 Curtailment Order (Methodology Steps 5 & 6)* ("*July As-Applied Order*"), which applied steps 5 and 6 of the *Methodology Order*. The Director predicted a revised IDS of 75,300 acre-feet. *July As-Applied Order*, at 8. Once again, he found TFCC to be the only member of the SWC predicted to experience material injury during the 2025 irrigation season, with an estimated Time of Need of August 28, 2025. *Id*. at 8–9.

6. Consequently, the Director ordered that by "July 24, 2025, ground water users holding consumptive water rights bearing priority dates junior to October 11, 1900, within the [ESPA ACGWS] shall establish, to the satisfaction of the Director, that they can mitigate for their proportionate share of the predicted IDS of 75,300 acre-feet in accordance with an approved mitigation plan." *Id.* at 12. He ordered that if such a junior ground water user cannot establish that they can mitigate for their proportionate share of the updated predicted IDS "in accordance with an approved mitigation plan, the Director will issue an order curtailing the junior-priority ground water user." *Id.* Additionally, the Director ordered "that the May 16, 2025 *Curtailment Order* remains in full force and effect." *Id*.

7. There are currently five approved mitigation plans in place responding to the SWC delivery call:

(1) Docket No. CM-MP-2010-001 for the benefit of the Southwest Irrigation District and Goose Creek Irrigation District (collectively, "SWID");

(2) Docket No. CM-MP-2019-001 for the benefit of certain cities commonly referred to as the "Coalition of Cities";

(3) Docket No. CM-MP-2015-003 for the benefit of the A&B Irrigation District ("A&B");

(4) Docket No. CM-MP-2007-001 for the benefit of certain entities commonly referred to as the "Water Mitigation Coalition"; and

(5) Docket No. CM-MP-2024-003 for the benefit of certain ground water districts commonly referred to as the "Ground Water Districts."

8. In both the *April Forecast Supply Order* and *July As-Applied Order*, the Director concluded that due to the nature of the approved mitigation plans for SWID, the Coalition of Cities, the Water Mitigation Coalition, and the Ground Water Districts, these entities do not need to establish they can mitigate for their proportionate share of the predicted IDS. *April Forecast Supply Order*, at 5 n.8; *July As-Applied Order*, at 11 n.6.

9. However, in the *July As-Applied Order* the Director concluded that A&B must mitigate for its proportionate share of the predicted July IDS of 75,300 acre-feet and determined that A&B's proportionate share is 5,039 acre-feet. *July As-Applied Order*, at 11 n.6. Although, he did note that in response to the *April Forecast Supply Order*, A&B previously demonstrated that it "already secured 164 acre-feet of storage water for the 2025 irrigation season." *Id*.

10. On July 24, 2025, A&B and the other members of the SWC submitted a *Joint Motion for Order Approving 2025 Stipulation* ("*Joint Motion*"). The motion explains that A&B and the other members of the SWC entered into a stipulation, referred to as the "*2025 Stipulation*," to "define A&B's mitigation obligation for the 2025 irrigation season." *Joint Motion*, at 2. In the stipulation, which is included as Attachment A to the *Joint Motion*, A&B proposes to continue its ground water conversions projects and deliver 1,252 acre-feet of storage water to TFCC (the injured SWC member) in accordance with its approved mitigation plan. *2025 Stipulation*, at 2. A&B and the other members of the SWC request the Director approve the *2025 Stipulation* as "stipulated compliance with [A&B's] approved mitigation plan for the 2025 irrigation season." *Joint Motion*, at 2. In an order issued concurrently with this order, the Director issued his *Order Approving 2025 Stipulation as Compliance with Approved Mitigation Plan*.

CONCLUSIONS OF LAW

1. Idaho Code § 42-602 authorizes the Director to supervise water distribution within water districts:

> The director of the department of water resources shall have direction and control of the distribution of water from all natural water sources within a water district to the canals, ditches, pumps and other facilities diverting therefrom. Distribution of water within water districts created pursuant to section 42-604, Idaho Code, shall be accomplished by watermasters as provided in this chapter and supervised by the director. The director of the department of water resources shall distribute water in water districts in accordance with the prior appropriation doctrine. The provisions of chapter 6, title 42, Idaho Code, shall apply only to distribution of water within a water district.

2. As explained above, by July 24, 2025, ground water users with consumptive water rights "junior to October 11, 1900, within the [ESPA ACGWS]" had to "establish, to the

satisfaction of the Director, that they can mitigate for their proportionate share of the predicted IDS of 75,300 acre-feet in accordance with an approved mitigation plan." *July As-Applied Order*, at 12. If a junior ground water user does not establish that they can mitigate for their proportionate share of the predicted July IDS "in accordance with an approved mitigation plan" the ground water user will be subject to this "order curtailing the junior-priority ground water user." *Id.*

3. Due to the nature of the approved mitigation plans for SWID, the Coalition of Cities, the Water Mitigation Coalition, and the Ground Water Districts, these entities do not need to establish that they can mitigate for their proportionate share of the predicted July IDS. Junior ground water users entitled to the protection of SWID, the Coalition of Cities, the Water Mitigation Coalition, and the Ground Water Districts mitigation plans continue to not be subject to curtailment during the 2025 irrigation season.

4. Under a separate order, the Director approved the *2025 Stipulation* between A&B and the other members of the SWC because it is consistent with A&B's approved mitigation plan in Docket No. CM-MP-2015-003. Accordingly, A&B's water rights will not be subject to curtailment during the 2025 irrigation season.

5. Consistent with the *July As-Applied Orde*r, Idaho Code § 42-602, and decisions of the courts, the Director must order curtailment of junior-priority ground water users that have not established they can mitigate in accordance with an approved mitigation plan. Junior-priority ground water users subject to curtailment are listed in the updated Attachments A to this order.

ORDER

Based upon and consistent with the foregoing, IT IS HEREBY ORDERED that effective July 25, 2025, ground water users holding water rights bearing priority dates junior to October 11, 1900, within the ESPA ACGWS, and listed in Attachment A to this order, shall curtail/refrain from diversion and use of ground water pursuant to those water rights unless notified by the Department that the order of curtailment has been modified or rescinded as to their water rights.

IT IS FURTHER ORDERED that holders of ground water rights listed in Attachment A to this order, who were not previously listed in Attachment A to the May 16, 2025 *Curtailment Order*, may seek to participate in an approved mitigation plan through a ground water district and shall have fifteen days from the date of this order to join, solely for mitigation purposes, the ground water district situated nearest the lands to which the water rights are appurtenant. *See* H.B. 737a, 58th Leg., 2d Reg. Sess. (Idaho 2006) (*Act Relating to the Administration of Ground Water Rights Within the Eastern Snake River Plain*); *see also* I.C. § 42-5259. The water rights that have fifteen days to join a ground water district are identified in Attachment A.

IT IS FURTHER ORDERED that watermasters for the water districts within the ESPA ACGWS who regulate ground water are directed to review the water rights listed in Attachment A to this order and begin the curtailment process.

IT IS FURTHER ORDERED that this order shall apply to consumptive ground water rights, including but not limited to, agricultural, commercial, industrial, and municipal uses. This order excludes ground water rights used for *de minimis* domestic purposes where such domestic use is within the limits of the definition set forth in Idaho Code § 42-111 and ground water rights used for *de minimis* stock watering where such stock watering use is within the limits of the definitions set forth in Idaho Code § 42-1401A(11), pursuant to IDAPA 37.03.11.020.11.

Dated this 25th day of July 2025.

EXPLANATORY INFORMATION TO ACCOMPANY A FINAL ORDER

(To be used in connection with actions when a hearing was **not** held)

The accompanying document is a "**Final Order**" issued by the Idaho Department of Water Resources ("Department") pursuant to Idaho Code § 67-5246.

PETITION FOR RECONSIDERATION

(*See* Idaho Code § 67-5246(4))

Any party may file a petition for reconsideration of this final order within fourteen (14) days of the service date of this order as shown on the certificate of service. **Note: the petition must be received by the Department within this fourteen (14) day period.** The presiding officer will act on a petition for reconsideration within twenty-one (21) days of its receipt, or the petition will be considered denied by operation of law.

REQUEST FOR HEARING

(*See* Idaho Code § 42-1701A(3))

Unless the right to a hearing before the Department or the Water Resource Board is otherwise provided by statute, any person aggrieved by any final decision, determination, order or action of the Director, and who has not previously been afforded an opportunity for a hearing on the matter may request a hearing pursuant to Idaho Code § 42-1701A(3). A written petition to the Director contesting this final order and requesting a hearing must be filed with the Department by any aggrieved person **within fifteen (15) days after service of this final order**.

CERTIFICATE OF SERVICE

(*See* IDAPA 37.01.01.053, 37.01.01.202)

All documents filed with the Department in connection with a petition for reconsideration or a request for hearing of this final order shall be served on all other parties to the proceedings in accordance with Rules of Procedure 53 and 202.

BEFORE THE DEPARTMENT OF WATER RESOURCES

OF THE STATE OF IDAHO

IN THE MATTER OF DISTRIBUTION OF WATER TO VARIOUS WATER RIGHTS HELD BY OR FOR THE BENEFIT OF A&B IRRIGATION DISTRICT, AMERICAN FALLS RESERVOIR DISTRICT #2, BURLEY IRRIGATION DISTRICT, MILNER IRRIGATION DISTRICT, MINIDOKA IRRIGATION DISTRICT, NORTH SIDE CANAL COMPANY, AND TWIN FALLS CANAL COMPANY	Docket No. CM-DC-2010-001 **ORDER REVISING JULY 2025 FORECAST SUPPLY** ***(METHODOLOGY STEPS 7–8)***

The Director of the Idaho Department of Water Resources ("Department") finds, concludes, and orders as follows:

FINDINGS OF FACT

A. Background

1. On July 19, 2023, the Director issued the *Sixth Final Order Regarding Methodology for Determining Material Injury to Reasonable In-Season Demand and Reasonable Carryover* ("*Methodology Order*"). The *Methodology Order* established nine steps for determining material injury to members of the Surface Water Coalition ("SWC"). This order applies Steps 7 and 8 of the *Methodology Order*.

2. On April 16, 2025, the Director issued the *Final Order Regarding April 2025 Forecast Supply (Methodology Steps 1–3)* ("*April Forecast Supply Order*"). The *April Forecast Supply Order* predicted a demand shortfall to the SWC of 63,000 acre-feet for the 2025 irrigation season. *April Forecast Supply Order* at 3. At that time, the only member of the SWC predicted to experience material injury during the 2025 irrigation season was Twin Falls Canal Company ("TFCC"). The Director ordered that, by May 1, 2025, ground water users with consumptive water rights "junior to August 28, 1955, within the Eastern Snake Plain Aquifer area of common ground water supply shall establish, to the satisfaction of the Director, that they can mitigate for their proportionate share of the predicted April IDS [(in-season demand shortfall)] of 63,000 acre-feet in accordance with an approved mitigation plan." *Id.* at 6. The Director also ordered that, "[i]f a junior ground water user cannot establish . . . that they can mitigate for their proportionate share of the predicted April IDS in accordance with an approved mitigation plan, the Director will issue an order curtailing the junior-priority ground water user." *Id.*

3. On May 16, 2025, the Director issued a *Final Order Curtailing Ground Water Rights Junior to August 28, 1955* ("*First Curtailment Order*"). The Director ordered that:

> [E]ffective May 31, 2025, ground water users holding water rights bearing priority dates junior to August 28, 1955, within the ESPA ACGWS, and listed in Attachment A to this order, shall curtail/refrain from diversion and use of ground

water pursuant to those water rights unless notified by the Department that the order of curtailment has been modified or rescinded as to their water rights.

First Curtailment Order at 4.

4. On July 10, 2025, the Director issued the *Order Revising April 2025 Forecast Supply and Continuing May 16, 2025 Curtailment Order (Methodology Steps 5 & 6)* ("*July Forecast Supply Order*"), revising the IDS to 75,300 acre-feet. *July Forecast Supply Order* at 8. The Director ordered that:

> On or before July 24, 2025, ground water users holding consumptive water rights bearing priority dates junior to October 11, 1900, within the Eastern Snake Plain Aquifer area of common ground water supply shall establish, to the satisfaction of the Director, that they can mitigate for their proportionate share of the predicted IDS of 75,300 acre-feet in accordance with an approved mitigation plan. If a junior ground water user cannot establish, to the satisfaction of the Director, that they can mitigate for their proportionate share of the predicted IDS of 75,300 acre-feet in accordance with an approved mitigation plan, the Director will issue an order curtailing the junior-priority ground water user.

Id. at 12 (footnote omitted).

5. Step 7 of the *Methodology Order* requires:

> Shortly before the estimated Time of Need, but following the events described in Steps 5 and 6, the Director will, for each member of the SWC: (1) recalculate RISD [(reasonable in-season demand)]; (2) issue a revised FS [(forecast supply)]; and (3) establish the Time of Need. The revised FS for each SWC entity is the sum of the year-to-date actual natural flow diversions, the forecasted natural flow supply for the remainder of the season, and the storage allocation for each member of the SWC. The forecasted natural flow supply for the remainder of the season will be based on analogous year(s) with similar Blackfoot to Milner reach gains. The storage allocation will be based on the actual preliminary storage allocations issued by the BOR [(United States Bureau of Reclamation)] and Water District 01.
>
> This information will be used to recalculate RISD and adjust the projected IDS for each member of the SWC. RISD will be calculated utilizing the project efficiency, BD [(baseline year demand)], and the cumulative actual CWN [(crop water need)] determined up to that point in the irrigation season. The Director will then issue revised RISD and IDS values.
>
> A transient ESPAM simulation will be run to determine the priority date of water rights that must be curtailed to produce the demand shortfall volume by September 30 of the same year. Curtailment will be simulated within the area of common ground water supply, as described by CM Rule 50.01.

Methodology Order at 44.

6. Effective July 1, 2024, Senate Bill 1341 added a new section to Idaho Code, Idaho Code § 42-233c, which codified the description of the ESPA area of common ground water supply. S.B. 1341, 67th Leg., 2d Reg. Sess. (Idaho 2024). The current area of common ground water supply for the Eastern Snake Plain Aquifer is defined as the aquifer underlying the Eastern Snake River Plain as described in the model calibration report for ESPAM2.2, dated May 2021. I.C. § 42-233c(1).

7. Step 8 of the *Methodology Order* requires:

> At the Time of Need, junior ground water users are required to deliver to each injured member of the SWC the Step 7 revised IDS calculated at the Time of Need. Alternatively, any additional mitigation obligation calculated in Step 6 and Step 7 can be satisfied from each SWC member's reasonable carryover if (a) the reasonable carryover exceeds the additional mitigation obligation, and (b) the junior ground water users secure sufficient water to replace the reasonable carryover pursuant to an approved mitigation plan.
>
> The Director will review, at the end of the season, the volume and efficiencies of application of surface water, the amount of mitigation water delivered by junior ground water users, and may, in the exercise of his professional judgment, readjust the reasonable carryover shortfalls to reflect these considerations.

Methodology Order at 44–45.

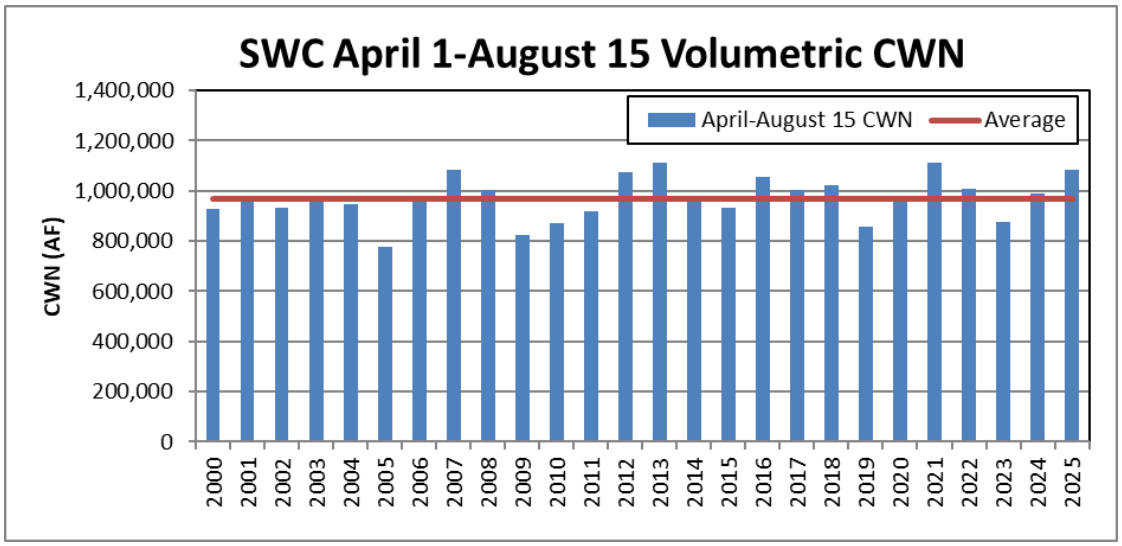
B. Climate

8. The April 2025 Joint Forecast prepared by the United States Army Corps of Engineers and the United States Bureau of Reclamation ("BOR") predicted 3,380,000 acre-feet of natural flow at the Heise gage for the period April–July 2025. *April Forecast Supply Order* at 2. The Joint Forecast "is generally as accurate a forecast as is possible using current data gathering and forecasting techniques." *Methodology Order* at 19.

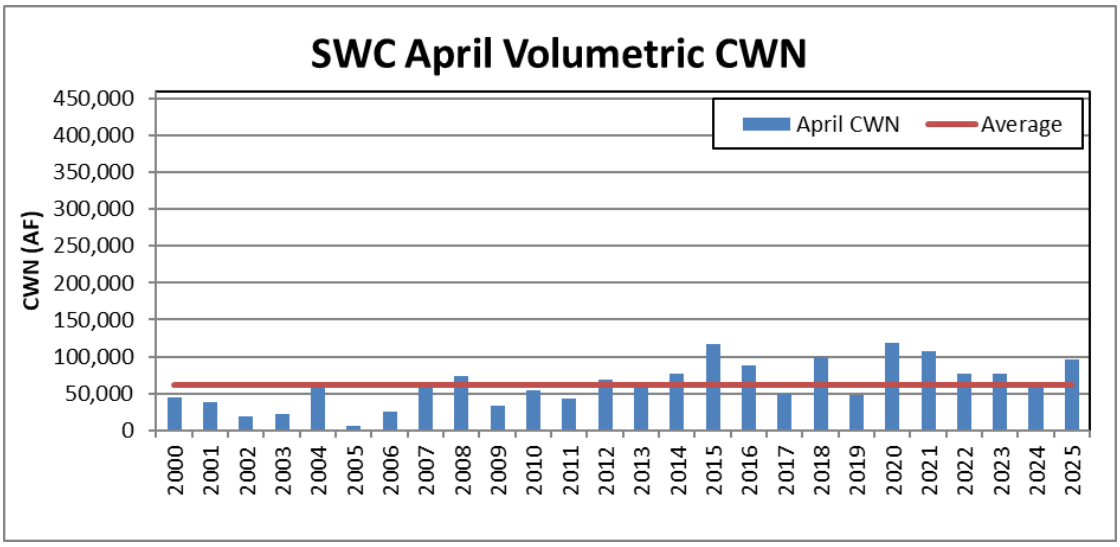
9. The April through July precipitation was below average, while the April through July temperature was above average.[1] The National Weather Service's Twin Falls weather station reported 9%, 38%, 0%, and 68% of normal precipitation in April, May, June, and July, respectively. Twin Falls temperatures were 2.5, 3.8, 3.4, and 2.2 degrees above normal for April, May, June, and July, respectively. According to data measured at the Natural Resources Conservation Service's SNOTEL sites in the Upper Snake River Basin, the basin received 73%, 74%, 19%, and 66% of average precipitation in April, May, June, and July, respectively.[2]

[1] Precipitation and temperature data obtained from the NOAA National Weather Service Preliminary Monthly Climate Data for the Twin Falls weather station (Twin Falls Airport).

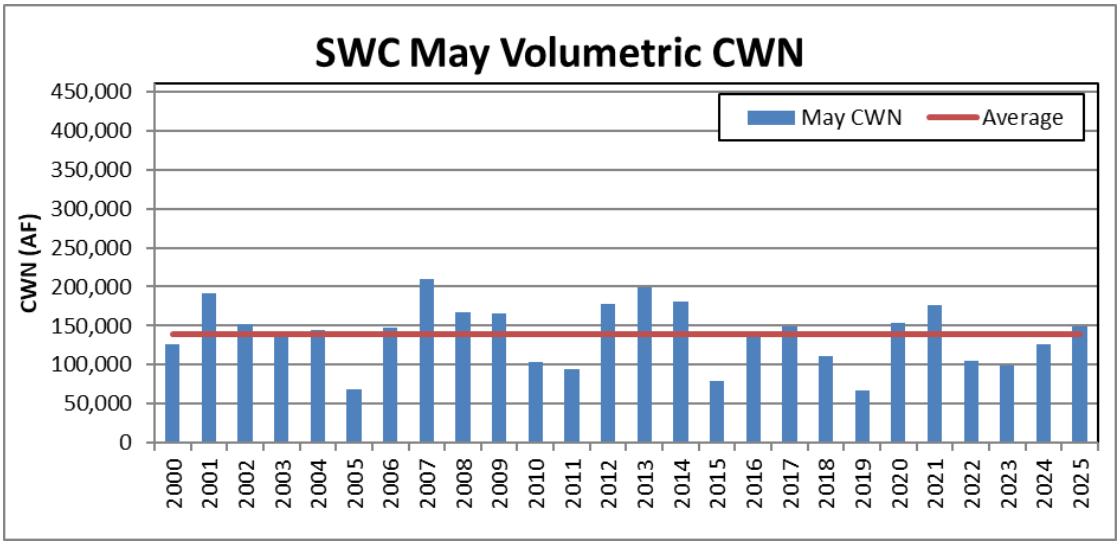
[2] Natural Resources Conservation Service's (NRCS) SNOTEL precipitation in the Upper Snake River Basin has been updated by the NRCS since the *Order Revising April 2025 Forecast Supply and Continuing May 16, 2025 Curtailment Order* was issued.



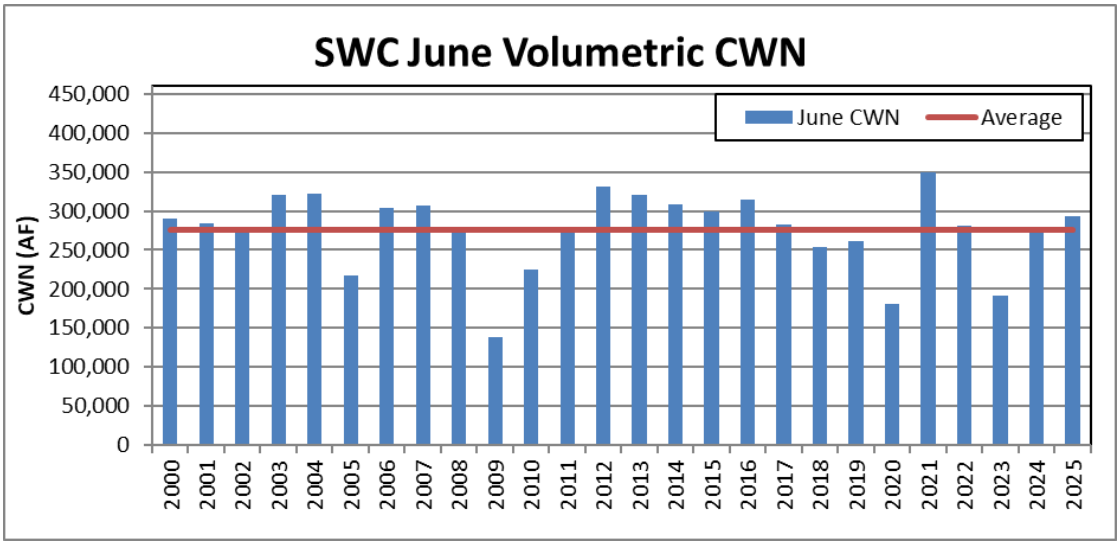
C. Reasonable In-Season Demand



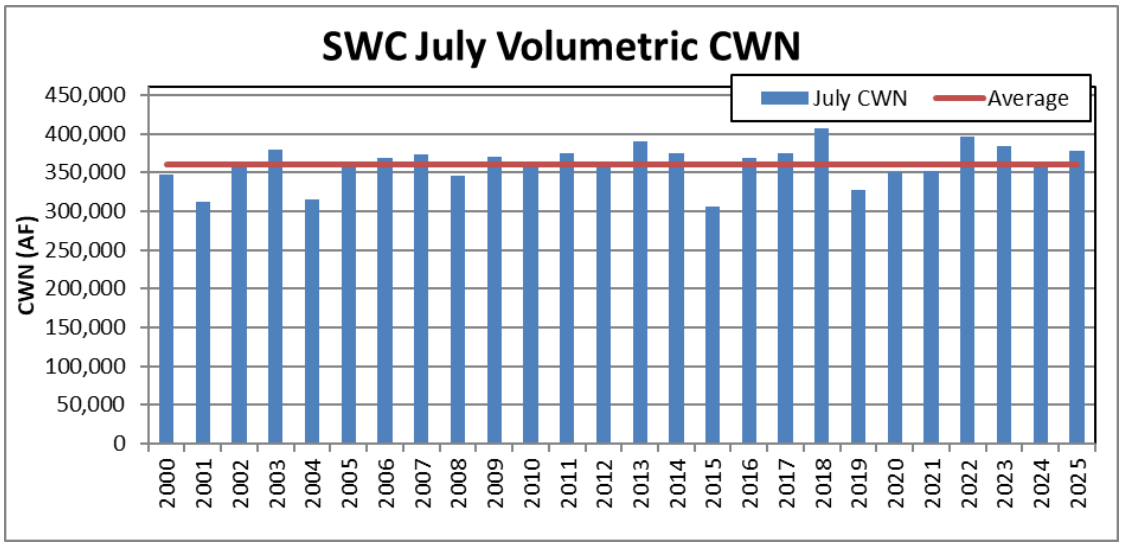
10. RISD is the volume of water that would be required to be diverted at the point of diversion during the year of evaluation to grow the specific crops within the service area of the entity. In April, the demand from the 2018 baseline year (BLY) represents the RISD. During the irrigation season, the RISD for the already expired portion of the irrigation season is recalculated by dividing the actual crop water need (CWN) for each entity by the project efficiency for that entity. For the future remainder of the irrigation season, the RISD is the demand predicted from the 2018 BLY. RISD is calculated on a monthly timestep.



i. Crop Water Need



11. CWN is the project wide volume of irrigation water required for crop growth so crop development is not limited by water availability. CWN is the difference between the fully realized consumptive use associated with crop development, or evapotranspiration, and effective precipitation. CWN is an input variable for calculating RISD for those months of the irrigation season that are complete. Actual RISD for the completed portion of the irrigation season is combined with monthly predicted baseline demands for the remaining months of the irrigation season to calculate a season-total RISD volume. Demand shortfall is then calculated as the difference between the adjusted forecast supply and the RISD. For specifics regarding determination of CWN, see page 15 of the *Methodology Order*.



12. As calculated from the beginning of the irrigation season (April 1), the SWC's volumetric CWN for the current water year through August 15 is 1,083,069 acre-feet. This volume is 110% of the April 1 through August 15 ten-year average CWN (2015-2024) and 106% of the CWN for the (2018) BLY. As calculated from April 1 through August 15, from the year 2000 to now, 2025 has the fourth largest CWN volume of any irrigation season. The following graphs summarize monthly volumetric CWN values.

ii. Extension of BLY

13. The RISD for the future portion of the irrigation season is the August 16–October 31 demand for (2018) BLY. The numeric August 16–October 31 demand values are shown in the table in Finding of Fact 14 below.

iii. Calculation of RISD

14. As calculated from the beginning of the irrigation season (April 1), the SWC's volumetric RISD for 2025 through August 15 is 2,537,439 acre-feet. This volume is 112% of the April 1–August 15 ten-year average RISD (2015-2024) and 105% of the April 1–August 15 demand for the (2018) BLY. As calculated from April 1 to August 15, from the year 2000 until this year, 2025 has the fifth largest RISD volume of any irrigation season. The recalculated RISD on August 15 of the 2025 irrigation season by entity is summarized in column six of the following table:

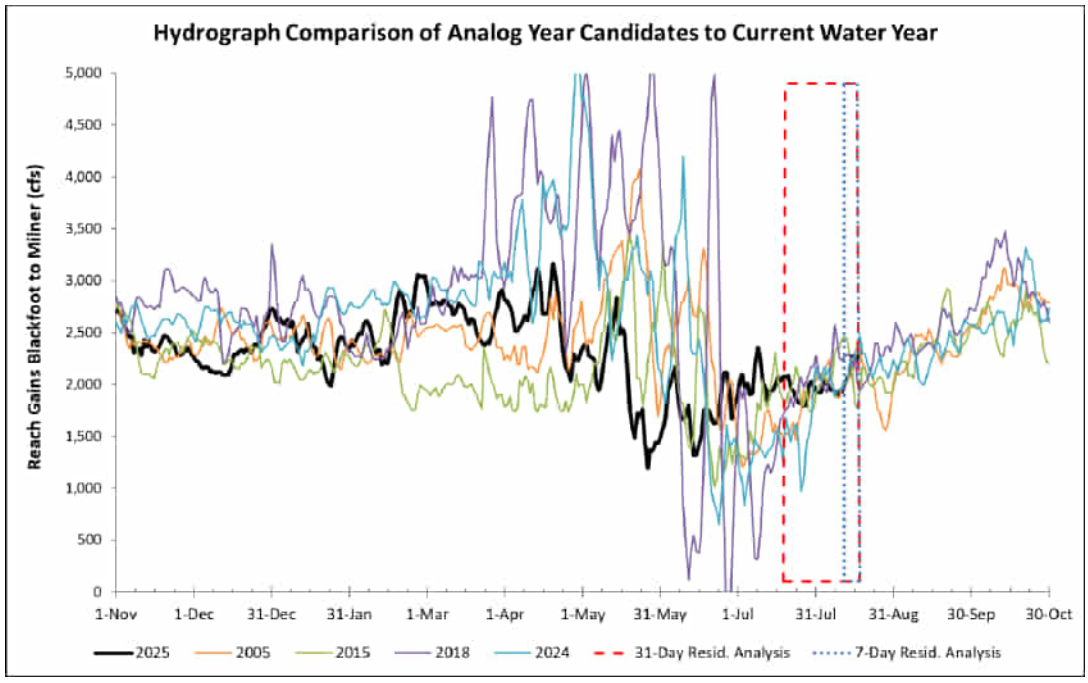
	April 1–August 15 CWN (AF)	Range of April 1–August 15 Monthly Project Efficiencies	April 1–August 15 RISD (AF)	August 16–October 31 Demand for 2018 BLY (AF)	Recalculated RISD (AF)
A&B	29,276	0.41-0.92	47,932	16,216	64,148
AFRD2	121,490	0.20-0.44	339,309	138,946	478,255
BID	88,126	0.30-0.52	201,896	63,932	265,828
Milner	25,828	0.36-0.68	45,207	16,031	61,238
Minidoka	159,119	0.36-0.65	307,036	86,518	393,554
NSCC	281,341	0.21-0.48	752,214	276,703	1,028,917
TFCC	377,888	0.27-0.59	843,845	330,074	1,173,919

D. Forecast Supply

15. When determined during the irrigation season, the forecast supply (FS) is the sum of the year-to-date actual natural flow diversions, the forecasted natural flow supply for the remainder of the season, and storage allocations for each member of the SWC. *Methodology Order* at 43. Actual natural flow diversions for the already expired portion of the irrigation season are extracted from the Department's water rights accounting program. The forecasted natural flow supply for the remainder of the irrigation season is based on the selection of an analogue year with similar Blackfoot to Milner reach gains. *Id*. at 44. Storage allocations are established by the BOR and Water District 01 ("WD1") after the day of allocation. *Id*.

i. Sum of Actual Natural Flow Diverted

16. Actual natural flow diverted for the period April 1 through August 15 for each SWC member are summarized in the table contained within the Summary of Forecast Supply section in Finding of Fact 21.



ii. Selection of an Analogous Year to Predict Remaining Natural Flow

17. Natural flow diversions for the remainder of the irrigation season were predicted by choosing an analogue year. The Department used a residual analysis[3] completed on a daily time step to compare the reach gains from July 19 to August 18 for the current water year to historical reach gains for the same period for the 1991–2024 water years. Based on its residual analysis and a qualitative review, the Department selected four candidate years: 2005, 2015, 2018, and 2024. These years represent the four years with the most similar reach gains (i.e., the lowest average residual value over a specified range) over the analysis period and the residuals are summarized in the following table:

Summary of Residual Analysis of Candidate Years

Time Period	2005	2015	2018	2024
7-Day (8/12 – 8/18)	0.2%	1.9%	-0.7%	-2.4%
31-Day (7/19 – 8/18)	3.3%	-2.3%	-4.9%	7.9%

18. The following hydrograph compares the current water year to the four candidate years with the most similar reach gains as determined by the residual analysis and qualitative review. The Department examined natural flow diversions for each of the candidate years and selected 2005 as the analogue year used to predict natural flow diversions for the remainder of the irrigation season. The Department chose 2005 because the residual analysis and qualitative review demonstrated 2005 was most like 2025 conditions when considering the reach gains for the most recent 7-day and 31-day periods.

[3] The daily residual is expressed as a percentage and defined as the difference between the current water year reach gain (CY) and the historical reach gain (HY) divided by the current water year reach gain: R = (CY – HY)/CY.

iii. Storage Allocations

19. Preliminary storage allocation values for each member of the SWC were established by the BOR and WD1 and published in WD1's preliminary Storage Report on July 15, 2025.[4] Storage allocation values for each SWC member are summarized in the table in Finding of Fact 21 below.

iv. Adjustments to Total Supply

20. The natural flow and storage water supplies were both adjusted as shown in the table in Finding of Fact 21 below. Adjustments to natural flow include water delivered to Southwest Irrigation District by BID and Milner, 691 acre-feet and 560 acre-feet, respectively . Adjustments to natural flow also include 1,441 acre-feet and 400 acre-feet of recharge water, delivered by the AFRD2 and BID, respectively, for the Idaho Water Resource Board. The only adjustments made to the stored water supply were for the Minidoka Return Flow Credit.[5] The Department did not adjust SWC water supplies for wheeled storage water published in WD1's weekly reports because wheeled water does not increase the amount of water available for use by the SWC. The Department did not adjust SWC water supplies to account for water supplied to or from the rental pool because these transactions artificially increase or decrease the shortfall obligation.

v. Summary of Forecast Supply

21. The table below contains the individual components of the FS for each of the SWC members.

	April 1–August 15 Natural Flow Diverted (AF)	August 16–October 31 Predicted Natural Diversions Flow (AF)	Natural Flow Adjustment (AF)	Preliminary Storage Allocation (AF)	Minidoka Credit Adjustment (AF)	Forecast Supply (AF)
A&B	9,547	0	0	120,473	0	130,020
AFRD2	90,640	0	(1,441)	383,912	1,000	474,111
BID	123,935	8,282	(1,091)	214,990	5,130	351,246
Milner	14,114	305	(560)	80,506	0	94,365
Minidoka	156,842	10,480	0	338,930	8,370	514,622
NSCC	385,639	54,218	0	798,776	(7,750)	1,230,883
TFCC	626,598	261,530	0	232,941	(6,750)	1,114,319

[4] The preliminary Storage Report may be viewed at: https://www.waterdistrict1.com/media/yxefjahy/2025-07-15-preliminary-storage-report.pdf.

[5] For an explanation of the Minidoka Credit, see pages 126-127 of *Concepts, Practices, and Procedures Used to Distribute Water Within Water District #1*, which can be found at: https://www.waterdistrict1.com/media/uabos05r/wd01-procedures-manual-4-12-2023.pdf

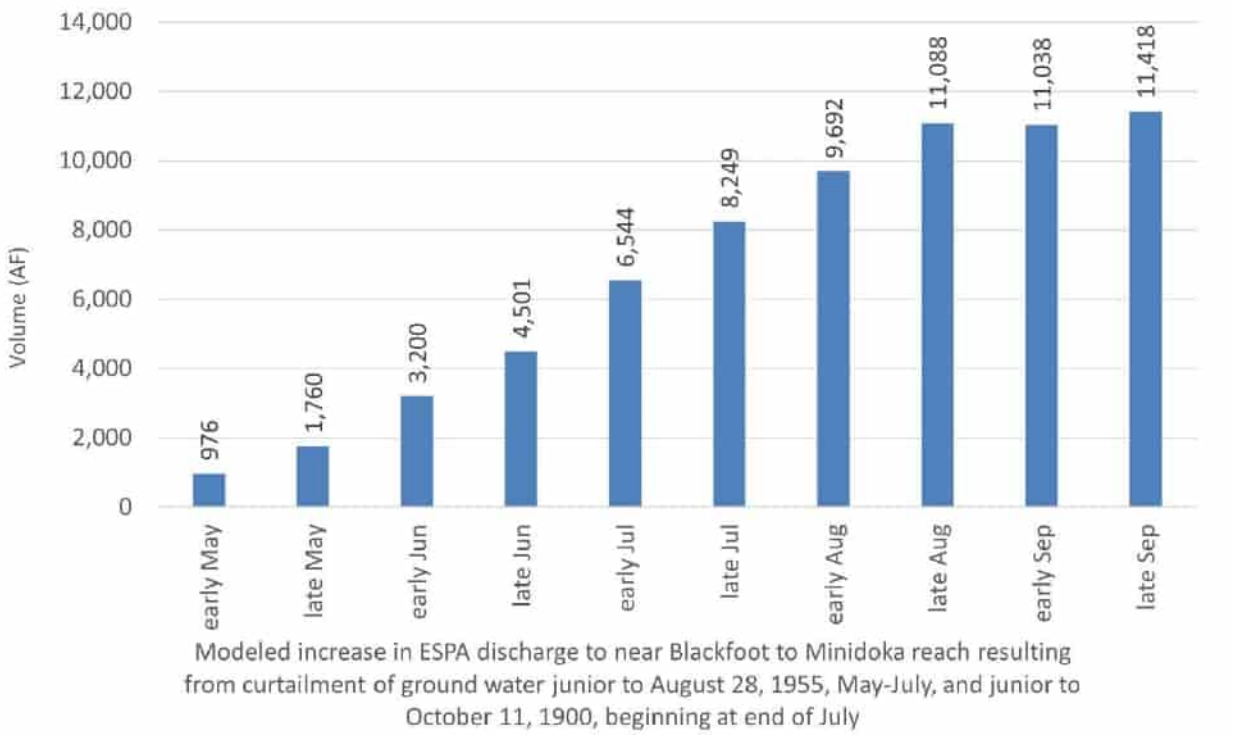
E. Revised Shortfall Prediction

22. Demand Shortfall is calculated as the difference between RISD and the FS.

23. Based on the methods described above, and as summarized in the following table, the Director predicts, at this time, that AFRD2 and TFCC will be materially injured by junior ground water pumping.

	Forecast Supply (AF)	RISD (AF)	Shortfall (AF)
A&B	130,020	64,148	0
AFRD2	474,111	478,255	4,100
BID	351,246	265,828	0
Milner	94,365	61,238	0
Minidoka	514,622	393,554	0
NSCC	1,230,883	1,028,917	0
TFCC	1,114,319	1,173,919	59,600
		Total	63,700

24. The current, predicted shortfall to the SWC's RISD is 63,700 acre-feet.



F. Time of Need

25. The Department established the Time of Need by predicting when the remaining storage balance for TFCC was equal to their reasonable carryover volume of 37,400 acre-feet and the remaining storage balance for AFRD2 was equal to their reasonable carryover volume of 16,700 acre-feet. As described above, the Department selected 2005 as the analogue year it used to predict the storage use for TFCC and AFRD2 for the remainder of this season. Anticipating that TFCC's and AFRD2's storage use for the remainder of the 2025 season will be similar to their storage use in 2005, TFCC's Time of Need occurred on August 16, 2025, and AFRD2's Time of Need will occur on September 28, 2025.

G. Priority and Curtailment

26. In April 2025, pursuant to the *Methodology Order*, the Department ran the Eastern Snake Plain Aquifer Model version 2.2 ("ESPAM2.2") to calculate the priority curtailment date, such that the curtailment of all water rights junior to the date within the area of common ground water supply, would produce a volume of water equal to the April IDS in the Snake River between May 1 and September 30. The ESPAM2.2 simulation predicted curtailment of ground water rights bearing priority dates junior to August 28, 1955, would produce the volume of water equal to the predicted April IDS of 63,000 AF in the near Blackfoot to Minidoka reach. *April Forecast Supply Order*, at 4.

27. In the *July Forecast Supply Order*, the Director predicted a demand shortfall to the SWC of 75,300 acre-feet. In July 2025, the Department ran the ESPAM2.2 to simulate the effect of adjusting the curtailment priority date at the end of July. The ESPAM2.2 simulation calculated that the curtailment of ground water rights junior to August 28, 1955, through the end of July followed by curtailment of groundwater rights junior to October 11, 1900,[6] would produce a volume of water of 58,000 AF in the near Blackfoot to Minidoka reach between July 1 and September 30 of this irrigation season. The following figure summarizes the results of the ESPAM2.2 simulation:

Modeled increase in ESPA discharge to near Blackfoot to Minidoka reach resulting from curtailment of ground water junior to August 28, 1955, May-July, and junior to October 11, 1900, beginning at end of July

28. The ESPAM2.2 simulation calculated that the curtailment of ground water rights junior to August 28, 1955, through the end of July followed by curtailment of groundwater rights junior to October 11, 1900, will produce a volume of water of 33,500 AF in the near Blackfoot to Minidoka reach between August 16 and September 30 of this irrigation season.

29. The predicted mid-August through September benefits to the near Blackfoot to Minidoka reach from curtailment of ground water rights bearing priority dates junior to August 28, 1955, through the end of July followed by curtailment of groundwater rights junior to October 11, 1900, are less than the August IDS of 63,700 acre-feet. Continuing the curtailment of ground water rights junior to October 11, 1900, will offset as much of the August IDS as possible.

[6] October 11, 1900, is the priority date equal to TFCC's Water Right No. 1-209, the most senior SWC natural flow water right predicted to be injured.

CONCLUSIONS OF LAW

1. Based on Findings of Fact 8 through 29 above, TFCC and AFRD2 are being materially injured. The updated predicted IDS is 63,700 acre-feet. The predicted shortfall to TFCC is 59,400 acre-feet. The predicted shortfall to AFRD2 is 4,100 acre-feet.

2. Based on current information, the Time of Need for TFCC occurred on August 16, 2025, and the Time of Need for AFRD2 will occur on September 28, 2025.

3. Pursuant to Step 8, at the Time of Need, junior ground water users are required to deliver to each injured member of the SWC the Step 7 revised IDS calculated at the Time of Need. Alternatively, any additional mitigation obligation calculated in Step 6 and Step 7 can be satisfied from each SWC member's reasonable carryover if (a) the reasonable carryover exceeds the additional mitigation obligation, and (b) the junior ground water users secure sufficient water to replace the reasonable carryover pursuant to an approved mitigation plan.

4. Using the ESPAM2.2, the Department has determined that the curtailment of ground water rights bearing priority dates junior to August 28, 1955, through the end of July followed by curtailment of groundwater rights junior to October 11, 1900, would result in a volume of water less than the predicted IDS of 63,700 acre-feet in the near Blackfoot to Minidoka reach between August 16 and September 30 of this irrigation season. Accordingly, continuing the curtailment to include ground water rights junior to October 11, 1900, is necessary for curtailment to offset as much of the IDS as possible.

5. Junior ground water users holding consumptive water rights bearing priority dates junior to October 11, 1900, within the Eastern Snake Plain Aquifer area of common ground water supply must mitigate for their proportionate share of the predicted July IDS in accordance with an approved mitigation plan.[7] For the 2025 irrigation season, there are no junior ground water users mitigating for their proportionate share of the predicted July IDS with a secured volume of water. Accordingly, no junior ground water users are required to deliver to each injured member of the SWC the Step 7 revised IDS calculated at the Time of Need.

[7] There are five approved mitigation plans responding to the SWC delivery call, the SWC stipulates to each: (1) No. CM-MP-2015-003 for the benefit of A&B; (2) No. CM-MP-2010-001 for the benefit of Southwest Irrigation District and Goose Creek Irrigation District (collectively, "SWID"); (3) No. CM-MP-2024-003 for the benefit of the Ground Water Districts; (4) No. CM-MP-2019-001 for the benefit of the Coalition of Cities; and (5) No. CM-MP-2007-001 for the benefit of the Water Mitigation Coalition. Given the nature of A&B's mitigation plan, the Department normally calculates A&B's proportionate share of the predicted IDS. However, A&B and the SWC entered into a stipulation to define A&B's mitigation obligation for the 2025 irrigation season. In the stipulation, A&B agreed to continue its ground water conversions projects and assign and deliver 1,252 acre-feet of storage water to TFCC. The Director has confirmed that 1,252 acre-feet of storage water has been assigned to A&B. Because the SWC agreed that the above actions satisfy A&B's obligation to the SWC for the 2025 irrigation season, A&B does not need to establish that they can mitigate for its proportionate share of the predicted IDS. Due to the nature of the mitigation plans for SWID, the Ground Water Districts, the Coalition of Cities, and the Water Mitigation Coalition, these entities do not need to establish that they can mitigate for their proportionate share of the predicted IDS.

ORDER

Based upon and consistent with the foregoing, IT IS HEREBY ORDERED the Director's revised in-season prediction is an in-season demand shortfall of 63,700 acre-feet.

IT IS FURTHER ORDERED that the July 25, 2025 *Curtailment Order* remains in full force and effect. All ground water users holding water rights listed in Attachment A to the July 25, 2025 *Curtailment Order* bearing priority dates junior to October 11, 1900, shall continue to be curtailed from diversion and use of ground water pursuant to those water rights unless they are mitigating in accordance with an approved mitigation plan or are notified by the Department that the order of curtailment has been modified or rescinded as to their water rights.

Dated this 11th day of September 2025.

MATHEW WEAVER
Director

EXPLANATORY INFORMATION TO ACCOMPANY A FINAL ORDER

(To be used in connection with actions when a hearing was **not** held)

The accompanying document is a "**Final Order**" issued by the Idaho Department of Water Resources ("Department") pursuant to Idaho Code § 67-5246.

PETITION FOR RECONSIDERATION

(*See* Idaho Code § 67-5246(4))

Any party may file a petition for reconsideration of this final order within fourteen (14) days of the service date of this order as shown on the certificate of service. **Note: the petition must be received by the Department within this fourteen (14) day period.** The presiding officer will act on a petition for reconsideration within twenty-one (21) days of its receipt, or the petition will be considered denied by operation of law.

REQUEST FOR HEARING

(*See* Idaho Code § 42-1701A(3))

Unless the right to a hearing before the Department or the Water Resource Board is otherwise provided by statute, any person aggrieved by any final decision, determination, order or action of the Director, and who has not previously been afforded an opportunity for a hearing on the matter may request a hearing pursuant to Idaho Code § 42-1701A(3). A written petition to the Director contesting this final order and requesting a hearing must be filed with the Department by any aggrieved person **within fifteen (15) days after service of this final order**.

CERTIFICATE OF SERVICE

(*See* IDAPA 37.01.01.053, 37.01.01.202)

All documents filed with the Department in connection with a petition for reconsideration or a request for hearing of this final order shall be served on all other parties to the proceedings in accordance with Rules of Procedure 53 and 202.

BEFORE THE DEPARTMENT OF WATER RESOURCES

OF THE STATE OF IDAHO

IN THE MATTER OF DISTRIBUTION OF WATER TO VARIOUS WATER RIGHTS HELD BY OR FOR THE BENEFIT OF A&B IRRIGATION DISTRICT, AMERICAN FALLS RESERVOIR DISTRICT #2, BURLEY IRRIGATION DISTRICT, MILNER IRRIGATION DISTRICT, MINIDOKA IRRIGATION DISTRICT, NORTH SIDE CANAL COMPANY, AND TWIN FALLS CANAL COMPANY	Docket No. CM-DC-2010-001 **FINAL ORDER ESTABLISHING 2025 REASONABLE CARRYOVER** ***(METHODOLOGY STEP 9)***

FINDINGS OF FACT

1. On July 19, 2023, the Director ("Director") of the Idaho Department of Water Resources ("Department") issued the *Sixth Final Order Regarding Methodology for Determining Material Injury to Reasonable In-Season Demand and Reasonable Carryover* ("*Methodology Order*"). The *Methodology Order* establishes nine steps for determining material injury to members of the Surface Water Coalition ("SWC"). This order applies step nine, the final step of the *Methodology Order*, for the 2025 water year.

2. The *Methodology Order* describes step 9 as follows:

> Step 9: Following the end of the irrigation season (on or before November 30), the Department will determine the total actual volumetric demand and total actual [crop water need] for the entire irrigation season. This information will be used for the analysis of reasonable carryover shortfall, selection of future [base line years], and for the refinement and continuing improvement of the method for future use.
>
> On or before November 30, the Department will issue estimates of actual carryover and reasonable carryover shortfall volumes for all members of SWC. These estimates will be based on, but not limited to, the consideration of the best available water diversion and storage data from Water District 01, return flow monitoring, comparative years, and [reasonable in-season demand]. These estimates will establish the obligation of junior ground water users in providing water to the SWC for reasonable carryover shortfall. Fourteen (14) days following the issuance by the Department of reasonable carryover shortfall obligations, junior ground water users will be required to establish, to the satisfaction of the Director, their ability to supply a volume of storage water or to conduct other approved mitigation activities that will provide water to the injured members of the SWC equal to the reasonable carryover shortfall for all injured members of the SWC. If junior ground water users cannot provide this information, the Director will issue an order curtailing junior ground water rights. A transient ESPAM simulation will be run to determine the priority date of water rights that must be curtailed to produce the reasonable

> carryover shortfall volume by September 30 of the following year. Curtailment will be simulated within the area of common ground water supply, as described by [Rule 50.01 of the Department's Rules for Conjunctive Management of Surface and Ground Water Resources].[1]

Methodology Order, at 45 (footnote added).

3. The following table summarizes the 2025 irrigation season diversions and crop water need for each SWC entity. All values are reported in acre-feet ("AF"). These values are used to determine entity-specific season-ending reasonable in-season demand ("RISD") values for the in-season demand shortfall table.

Entity	Demand[2]	Crop Water Need
A&B	66,772	33,341
AFRD2	478,369	152,966
BID	282,546	101,624
Milner	68,320	31,448
Minidoka	362,365	188,837
NSCC	1,053,354	353,302
TFCC	1,135,302	462,347

4. The following table summarizes the final calculated 2025 in-season demand shortfall values in AF, if any, for each member of the SWC. The values in this table are different from those in the April 16, 2025 *Final Order Regarding April 2025 Forecast Supply (Methodology Steps 1–3)* ("*April Forecast Supply Order*"), the July 10, 2025 *Order Revising April 2025 Forecast Supply and Continuing May 16, 2025 Curtailment Order (Methodology Steps 5 & 6)* ("*July Order*"), and the September 11, 2025 *Order Revising July 2025 Forecast Supply (Methodology Steps 7–8)* ("*September Order*"). The differences are due to changes in total supply and RISD that reflect diversion and ET data not available when the *April Forecast Supply Order*, the *July Order*, and the *September Order* were issued. The second column of the summary table contains the total natural flow diversions from April 1 to October 31 for each SWC member.[3] The third column summarizes the natural flow adjustments, which include natural flow delivered for recharge[4] and natural flow delivered to Southwest Irrigation District

[1] In 2024, the Idaho Legislature established a new area of common ground water supply boundary for the Eastern Snake Plain Aquifer in Idaho Code § 42-233c. The new boundary is currently the ESPAM2.2 model boundary, but the boundary may be expanded by the Director in the future. I.C. § 42-233c(1)–(2). The Department used the ESPAM2.2 model boundary in the model simulation for this order.

[2] The "Demand" for each SWC entity is equal to each entity's 2025 April–October diversions.

[3] The natural flow diverted was calculated from the preliminary daily water right accounting records located here: https://research.idwr.idaho.gov/apps/Hydrologic/Accounting/.

[4] Natural flow recharge values represent accomplished recharge through the Idaho Water Resource Board's recharge water rights as of October 31, 2025.

("SWID").[5] The fourth column contains the preliminary storage allocations reported from the July 15, 2025 Water District 01 storage report.[6] The fifth column summarizes storage adjustments due to the application of the Minidoka Credit.[7] The sixth column contains the total supply available to each SWC member and is calculated by summing columns two through five. The seventh column contains the calculated RISD. RISD is calculated for each SWC entity using demand, crop water need, and project efficiency. The demand shortfall in the last column is calculated by subtracting the RISD from the total supply. The demand shortfall is zero when the total supply exceeds the RISD. The completed application of the methodology order results in a final net in-season demand shortfall volume of 49,100 AF to TFCC for the 2025 irrigation season.

Entity	Natural Flow Diverted through 10/31	Natural Flow Adjustment	Preliminary Storage Allocation	In-Season Storage Allocation Adjustment	Total Supply	RISD	Demand Shortfall
A&B	9,547	-	120,473	-	130,020	56,868	0
AFRD2	90,666	(1,441)	383,912	1,000	474,137	443,825	0
BID	128,387	(2,197)	214,990	5,130	346,310	240,938	0
Milner	14,687	(1,111)	81,420	-	94,996	57,470	0
Minidoka	162,476	-	338,930	8,370	509,776	376,548	0
NSCC	448,541	(12,466)	798,776	(7,750)	1,227,101	968,232	0
TFCC	880,736	(988)	233,880	(6,750)	1,106,878	1,155,974	49,100

5. The following table summarizes the end of season reasonable carryover shortfall calculation for 2025. All values are reported in AF. The second column of the table contains the preliminary storage allocations reported from the July 15, 2025 Water District 01 storage report. The third column summarizes adjustments for storage water due to the application of the Minidoka Credit. The fourth column contains the total storage water use reported from the October 31, 2025 Water District 01 water right accounting report.[8] The fifth column summarizes adjustments for water delivered through the SWC member's canals for use by non-SWC members.[9] The sixth column contains the actual carryover volumes as defined by the *Methodology Order*, *see Methodology Order*, at 45, and is calculated by subtracting the sum of columns four and five from the sum of columns two and three. The seventh column contains the

[5] Further information regarding these adjustments is provided in Attachment A. *See* "Natural Flow Adjustment" column *infra* Attachment A.

[6] The preliminary storage allocations can be found on Water District 01's website: https://www.waterdistrict1.com/current-data/.

[7] The Minidoka Credit is a long existing exchange of stored water among AFRD2, BID, MID, NSCC, and TFCC that has been incorporated into an agreement of those entities and accepted by the SRBA district court. Further information regarding these adjustments is provided in Attachment A. *See* "In-Season Storage Adjustment" column *infra* Attachment A.

[8] Data retrieved from the preliminary daily water right accounting database between November 5–10, 2025.

[9] Further information regarding these adjustments is provided in Attachment A. *See* "Storage Use Adjustment" column *infra* Attachment A (Storage Use Adjustment values include storage assignments reported on the Water District 01 Rental Pool and Adjustment Worksheet as of November 5, 2025).

reasonable carryover volumes established in the *Methodology Order*. *Methodology Order*, at 31. The reasonable carryover shortfall in the last column is zero when the actual carryover is greater than the reasonable carryover, otherwise it is calculated as the difference between reasonable carryover and the actual carryover volume for each member of the SWC. Completed application of the Methodology determines AFRD2 has a reasonable carryover shortfall of 20,932 AF and TFCC has a reasonable carryover shortfall of 65,824 AF. No other members of the SWC have a reasonable carryover shortfall.

Entity	Preliminary Storage Allocation	In-Season Storage Allocation Adjustment	Storage Use	Storage Use Adjustment	Actual Carryover	Reasonable Carryover	Reasonable Carryover Shortfall
A&B	120,473	-	57,225	0	63,248	22,700	0
AFRD2	383,912	1,000	395,244	(6,100)	(4,232)	16,700	20,932
BID	214,990	5,130	157,262	0	62,858	0	0
Milner	81,420	-	55,878	(1,134)	26,676	16,100	0
Minidoka	338,930	8,370	199,017	(35)	148,318	0	0
NSCC	798,776	(7,750)	630,279	(13,000)	173,747	113,300	0
TFCC	233,880	(6,750)	257,166	(1,612)	(28,424)	37,400	65,824

6. The above determinations are based on water diversion and storage data from Water District 01. Although these preliminary numbers are subject to revision by Water District 01 during its final accounting for 2025, revisions will not become available until after issuance of this order. For this reason, these estimates establish the final obligation of junior ground water users in supplying water to the SWC for reasonable carryover shortfall. The above determination of reasonable carryover shortfall is carried forward from the *Methodology Order* and considers the best available water diversion and storage data, comparative water years, and RISD. *Methodology Order*, at 45.

CONCLUSIONS OF LAW

1. The *Methodology Order* states that, on or before November 30, the Director will estimate the SWC's reasonable carryover shortfall, if any, for 2025. *Id*. If a reasonable carryover shortfall is established, junior-priority ground water users shall have fourteen days to demonstrate, to the satisfaction of the Director, "their ability to supply a volume of storage water or to conduct other approved mitigation activities that will provide water to the injured members of the SWC equal to the reasonable carryover shortfall for all injured members of the SWC." *Id*.

2. The evidentiary standard to apply in conjunctive administration of hydraulically connected water rights is clear and convincing. *A&B Irr. Dist. v. Idaho Dept. of Water Resources*, 153 Idaho 500, 524, 284 P.3d 225, 249 (2012).

3. "Clear and convincing evidence refers to a degree of proof greater than a mere preponderance." *Idaho State Bar v. Topp*, 129 Idaho 414, 416, 925 P.2d 1113, 1115 (1996) (internal quotations removed). "Clear and convincing evidence is generally understood to be '[e]vidence indicating that the thing to be proved is highly probable or reasonably certain.'" *State*

v. Kimball, 145 Idaho 542, 546, 181 P.3d 468, 472 (2008) (citing *In re Adoption of Doe*, 143 Idaho 188, 191, 141 P.3d 1057, 1060 (2006)); *see also Idaho Dept. of Health & Welfare v. Doe*, 150 Idaho 36, 41, 244 P.3d 180, 185 (2010).

4. Consistent with Finding of Fact 5, the Director concludes by clear and convincing evidence there is a 20,932 AF volume of material injury to AFRD2's reasonable carryover and a 65,824 AF volume of material injury to TFCC's reasonable carryover. No other members of the SWC have a reasonable carryover shortfall.

5. Because not all junior ground water users are participants in an approved mitigation plan, the Director must determine a priority date for curtailment that will result in an accumulation of water to the reaches of the Snake River from which the SWC members divert, in an amount equal to the established reasonable carryover shortfall. The water must accrue to the near Blackfoot to Minidoka reach by September 30 of the following year. Using the Eastern Snake Plain Aquifer Model ("ESPAM") Version 2.2, the Director determines curtailment of ground water rights junior to August 15, 1952, is predicted to produce a volume of at least 86,756 AF in the near Blackfoot to Minidoka reach by September 30, 2026.

6. According to the *Methodology Order*, fourteen days following issuance of this order, which establishes the reasonable carryover shortfall obligation, junior ground water users must "establish, to the satisfaction of the Director, their ability to supply a volume of storage water or to conduct other approved mitigation activities that will provide water to the injured members of the SWC equal to the reasonable carryover shortfall for all injured members of the SWC." *Methodology Order*, at 45. Otherwise, "the Director will issue an order curtailing junior ground water rights." *Id*.

ORDER

Based upon the foregoing, IT IS HEREBY ORDERED that, junior ground water users holding consumptive ground water rights within the Eastern Snake Plain Aquifer area of common ground water supply bearing priority dates junior to August 15, 1952, must mitigate for the reasonable carryover shortfall of 86,756 AF in accordance with an approved mitigation plan.[10] If, within fourteen days following issuance of this order, a junior ground water user fails to establish, to the satisfaction of the Director, their ability to mitigate for the reasonable carryover shortfall of 86,756 AF in accordance with an approved mitigation plan, the Director will issue an order curtailing the junior-priority ground water use.

[10] Participants in the mitigation plans approved for the Ground Water Districts, SWID, the Coalition of Cities, and the Water Mitigation Coalition do not need to establish their ability to mitigate for their proportionate share of the reasonable carryover shortfall. However, due to the nature of A&B Irrigation District's approved mitigation plan, A&B must establish to the satisfaction of the Director its ability to mitigate for its proportionate share of the reasonable carryover shortfall, which is 457 AF.

IT IS FURTHER ORDERED that this final order concludes the application of the *Methodology Order* to the climatic, hydrologic, and agronomic facts of the 2025 irrigation season.

DATED this 21st day of November 2025.

MATHEW WEAVER
Director

EXPLANATORY INFORMATION TO ACCOMPANY A FINAL ORDER

(To be used in connection with actions when a hearing was **not** held)

The accompanying document is a "**Final Order**" issued by the Idaho Department of Water Resources ("Department") pursuant to Idaho Code § 67-5246.

PETITION FOR RECONSIDERATION

(*See* Idaho Code § 67-5246(4))

Any party may file a petition for reconsideration of this final order within fourteen (14) days of the service date of this order as shown on the certificate of service. **Note: the petition must be received by the Department within this fourteen (14) day period.** The presiding officer will act on a petition for reconsideration within twenty-one (21) days of its receipt, or the petition will be considered denied by operation of law.

REQUEST FOR HEARING

(*See* Idaho Code § 42-1701A(3))

Unless the right to a hearing before the Department or the Water Resource Board is otherwise provided by statute, any person aggrieved by any final decision, determination, order or action of the Director, and who has not previously been afforded an opportunity for a hearing on the matter may request a hearing pursuant to Idaho Code § 42-1701A(3). A written petition to the Director contesting this final order and requesting a hearing must be filed with the Department by any aggrieved person **within fifteen (15) days after service of this final order**.

CERTIFICATE OF SERVICE

(*See* IDAPA 37.01.01.053, 37.01.01.202)

All documents filed with the Department in connection with a petition for reconsideration or a request for hearing of this final order shall be served on all other parties to the proceedings in accordance with Rules of Procedure 53 and 202.

BEFORE THE DEPARTMENT OF WATER RESOURCES

OF THE STATE OF IDAHO

IN THE MATTER OF DISTRIBUTION OF WATER TO VARIOUS WATER RIGHTS HELD BY OR FOR THE BENEFIT OF A&B IRRIGATION DISTRICT, AMERICAN FALLS RESERVOIR DISTRICT #2, BURLEY IRRIGATION DISTRICT, MILNER IRRIGATION DISTRICT, MINIDOKA IRRIGATION DISTRICT, NORTH SIDE CANAL COMPANY, AND TWIN FALLS CANAL COMPANY	Docket No. CM-DC-2010-001 **FINAL ORDER CURTAILING GROUND WATER RIGHTS JUNIOR TO AUGUST 15, 1952**

The Director of the Idaho Department of Water Resources ("Department") finds, concludes, and orders as follows:

FINDINGS OF FACT

1. On July 19, 2023, the Department issued its *Sixth Final Order Regarding Methodology for Determining Material Injury to Reasonable In-Season Demand and Reasonable Carryover* ("*Methodology Order*"). The *Methodology Order* established nine steps for determining material injury to members of the Surface Water Coalition ("SWC").[1]

2. On November 21, 2025, the Director issued the *Final Order Establishing 2025 Reasonable Carryover (Methodology Step 9)* ("*Step 9 Order*"). Therein, the Director concluded there is a 65,824-acre-foot ("AF") volume of material injury to Twin Falls Canal Company's reasonable carryover and a 20,932 AF volume of material injury to AFRD2. *Step 9 Order*, at 5. The Director concluded no other members of the SWC have a reasonable carryover shortfall. *Id*.

3. The Director ordered that within fourteen days of November 21, 2025, "junior ground water users holding consumptive ground water rights within the Eastern Snake Plain Aquifer area of common ground water supply bearing priority dates junior to August 15, 1952, must mitigate for the reasonable carryover shortfall of 86,756 AF in accordance with an approved mitigation plan." *Id*. The Director also ordered that, if such junior ground water users cannot establish that they can mitigate for the reasonable carryover shortfall "in accordance with an approved mitigation plan, the Director will issue an order curtailing the junior-priority ground water use." *Id.*

[1] The SWC is comprised of A&B Irrigation District, American Falls Reservoir District #2, Burley Irrigation District, Milner Irrigation District, Minidoka Irrigation District, North Side Canal Company, and Twin Falls Canal Company.

4. There are currently five approved mitigation plans in place responding to the SWC delivery call:[2]

(1) Docket No. CM-MP-2007-001 for the benefit of J.R. Simplot Company, Basic American Foods, and ConAgra Foods Packaged Foods Company, Inc., d/b/a Lamb-Weston (collectively, the "Water Mitigation Coalition");

(2) Docket No. CM-MP-2010-001 for the benefit of the Southwest Irrigation and Goose Creek Irrigation Districts (collectively, "SWID");

(3) Docket No. CM-MP-2015-003 for the benefit of the A&B Irrigation District ("A&B");

(4) Docket No. CM-MP-2019-001 for the benefit of certain cities commonly referred to as the "Coalition of Cities," the City of Idaho Falls, and the City of Pocatello (collectively, the "Cities").

(5) Docket No. CM-MP-2024-003 for the benefit of Aberdeen-American Falls Ground Water District, Bingham Ground Water District, Bonneville-Jefferson Ground Water District, Carey Valley Ground Water District, Henry's Fork Ground Water District, Jefferson-Clark Ground Water District, Madison Ground Water District, Magic Valley Ground Water District, and North Snake Ground Water District (collectively, the "Ground Water Districts");

5. In the *Step 9 Order*, the Director found that due to the nature of the approved mitigation plans for the Water Mitigation Coalition, SWID, the Cities, and the Ground Water Districts, these entities do not need to establish that they can mitigate for their proportionate share of the reasonable carryover shortfall. *Step 9 Order*, at 5 n.10. However, the Director found that due to the nature of A&B's mitigation plan, A&B must establish to the satisfaction of the Director its ability to mitigate for its proportionate share of the reasonable carryover shortfall, which is 457 AF. *Id.*

6. In response to the *Step 9 Order's* requirement for A&B to establish how it will mitigate its proportionate share of the reasonable carryover shortfall, A&B submitted *A&B Irrigation District's Request for Hearing/Evidence of Ability to Mitigate* ("*Mitigation Response*"). In the *Mitigation Response*, A&B stated that it does not intend to submit a lease demonstrating that it has secured the required storage for the benefit of the injured SWC members at this time. *Mitigation Response* at 3. A&B acknowledged that this may result in the Director including A&B's junior priority water rights in the list of water rights subject to this curtailment order. *Id*.

CONCLUSIONS OF LAW

1. Idaho Code § 42-602 authorizes the Director to supervise water distribution within

[2] In addition, there are currently five mitigation plans pending before the Department that have not been approved: (1) CM-MP-2025-004 (Big Lost River Ground Water District); (2) CM-MP-2025-003 (Bingham); (3) CM-MP-2025-001 (Pancheri); (4) CM-MP-2024-004 (Falls Water Co.); and (5) CM-MP-2024-002 (Falls Irrigation District). Because these plans are unapproved, water users may not rely on them for protection from curtailment at this time. In addition, CM-MP-2025-002 (Simplot) is no longer an effective mitigation plan because it was approved only for the 2025 irrigation season.

water districts:

> The director of the department of water resources shall have direction and control of the distribution of water from all natural water sources within a water district to the canals, ditches, pumps and other facilities diverting therefrom. Distribution of water within water districts created pursuant to section 42-604, Idaho Code, shall be accomplished by watermasters as provided in this chapter and supervised by the director.
>
> The director of the department of water resources shall distribute water in water districts in accordance with the prior appropriation doctrine. The provisions of chapter 6, title 42, Idaho Code, shall apply only to distribution of water within a water district.

2. As explained above, within fourteen days of November 21, 2025, "junior ground water users holding consumptive ground water rights within the Eastern Snake Plain Aquifer area of common ground water supply bearing priority dates junior to August 15, 1952, must mitigate for the reasonable carryover shortfall of 86,756 AF in accordance with an approved mitigation plan." *Step 9 Order*, at 5. If a junior ground water user does not establish that they can mitigate for the reasonable carryover shortfall in accordance with an approved mitigation plan, the ground water user will be subject to this "order curtailing the junior-priority ground water use." *Id.*

3. Due to the nature of the approved mitigation plans for the Water Mitigation Coalition, SWID, the Cities, and the Ground Water Districts, these entities do not need to establish that they can mitigate for their proportionate share of the reasonable carryover shortfall. Junior ground water users entitled to protection under the Water Mitigation Coalition's, SWID's, the Cities', or the Ground Water Districts' approved mitigation plans will not be subject to curtailment related to the reasonable carryover shortfall.

4. A&B has failed to provide timely documentation that it has adequately secured the storage water necessary to mitigate fully for its obligation under its approved mitigation plan. Accordingly, to ensure that A&B's ground water rights junior to August 15, 1952, are curtailed during the 2026 irrigation season, the Director will include A&B's water rights junior to August 15, 1952, on the curtailment list in Attachment A to this order.

5. The Director concludes that junior-priority ground water users who have not established that they can mitigate for the reasonable carryover shortfall in accordance with an approved mitigation plan should be curtailed. Junior-priority ground water users subject to curtailment are listed in Attachment A to this order.[3]

[3] On November 26, 2025, the Director expanded the ESPA ACGWS to include the Little Lost River Tributary basin. The administration of the newly included area of the Little Lost River Tributary Basin will be phased-in to the SWC delivery call proceeding and junior ground water rights newly included in the ESPA ACGWS are not included in the attached curtailment list. The Director anticipates issuing additional orders related to the expansion of the ESPA ACGWS. After that, the Director will issue an order addressing how the water rights in the newly expanded ESPA ACGWS will be phased-in.

ORDER

Based upon and consistent with the foregoing, IT IS HEREBY ORDERED that effective December 8, 2025, ground water users holding water rights bearing priority dates junior to August 15, 1952, within the Eastern Snake Plain Aquifer area of common ground water supply ("ESPA ACGWS") and listed in Attachment A to this order, shall curtail/refrain from diversion and use of ground water pursuant to those water rights unless notified by the Department that the curtailment order has been modified or rescinded as to their water rights.

IT IS FURTHER ORDERED that holders of ground water rights listed in Attachment A to this order, who were not previously listed in Attachment A to the July 25, 2025 Curtailment Order, may seek to participate in an approved mitigation plan through a ground water district and shall have fifteen days from the date of this order to join, solely for mitigation purposes, the ground water district situated nearest the lands to which the water rights are appurtenant. *See* H.B. 737a, 58th Leg., 2d Reg. Sess. (Idaho 2006) (*Act Relating to the Administration of Ground Water Rights Within the Eastern Snake River Plain*); *see also* I.C. § 42-5259. The water rights that have fifteen days to join a ground water district are identified in Attachment A.

IT IS FURTHER ORDERED that watermasters for the water districts within the ESPA ACGWS who regulate ground water are directed to review the water rights listed in Attachment A to this order and begin the curtailment process.

IT IS FURTHER ORDERED that this order applies to consumptive ground water rights, including but not limited to, agricultural, commercial, industrial, and municipal uses. This order excludes ground water rights used for *de minimis* domestic purposes where such domestic use is within the limits of the definition set forth in Idaho Code § 42-111 and ground water rights used for *de minimis* stock watering where such stock watering use is within the limits of the definitions set forth in Idaho Code § 42-1401A(11), pursuant to IDAPA 37.03.11.020.11.

Dated 8th day of December 2025.

MATHEW WEAVER
Director

EXPLANATORY INFORMATION TO ACCOMPANY A FINAL ORDER

(To be used in connection with actions when a hearing was **not** held)

(Required by Rule of Procedure 740.02)

The accompanying order is a "**Final Order**" issued by the department pursuant to section 67-5246, Idaho Code.

PETITION FOR RECONSIDERATION

Any party may file a petition for reconsideration of a final order within fourteen (14) days of the service date of this order as shown on the certificate of service. **Note: The petition must be received by the Department within this fourteen (14) day period.** The department will act on a petition for reconsideration within twenty-one (21) days of its receipt, or the petition will be considered denied by operation of law. See section 67-5246(4), Idaho Code.

REQUEST FOR HEARING

Unless the right to a hearing before the director or the water resource board is otherwise provided by statute, any person who is aggrieved by the action of the director, and who has not previously been afforded an opportunity for a hearing on the matter shall be entitled to a hearing before the director to contest the action. The person shall file with the director, within fifteen (15) days after receipt of written notice of the action issued by the director, or receipt of actual notice, a written petition stating the grounds for contesting the action by the director and requesting a hearing. See section 42-1701A(3), Idaho Code. **Note: The request must be received by the Department within this fifteen (15) day period.**

Revised June 28, 2024

BEFORE THE DEPARTMENT OF WATER RESOURCES

OF THE STATE OF IDAHO

IN THE MATTER OF DISTRIBUTION OF WATER TO VARIOUS WATER RIGHTS HELD BY OR FOR THE BENEFIT OF A&B IRRIGATION DISTRICT, AMERICAN FALLS RESERVOIR DISTRICT #2, BURLEY IRRIGATION DISTRICT, MILNER IRRIGATION DISTRICT, MINIDOKA IRRIGATION DISTRICT, NORTH SIDE CANAL COMPANY, AND TWIN FALLS CANAL COMPANY	Docket No. CM-DC-2010-001 **ORDER PHASING IN ADMINISTRATION OF GROUND WATER RIGHTS RECENTLY INCLUDED IN THE ESPA ACGWS**

BACKGROUND

The Eastern Snake Plain Aquifer Area of Common Ground Water Supply ("ESPA ACGWS") is the administrative boundary for the Surface Water Coalition ("SWC") delivery call proceeding (Docket No. CM-DC-2010-001), the proceeding in which this order is being issued.

On November 26, 2025, the Director of the Idaho Department of Water Resources ("Department") expanded the ESPA ACGWS to include the portion of the Little Lost River basin that was not already included within the ESPA ACGWS. *See Order Expanding the Eastern Snake Plain Aquifer Area of Common Ground Water Supply to Include the Little Lost River Tributary Basin* (Nov. 26, 2025).

On December 15, 2025, the Director expanded the ESPA ACGWS to include the Raft River Basin. *See Order Expanding the Eastern Snake Plain Aquifer Area of Common Ground Water Supply to Include the Raft River Tributary Basin* (Dec. 15, 2025).

On January 13, 2026, the Director expanded the ESPA ACGWS to include the portion of the Big Lost River Basin that was not already included within the ESPA ACGWS. *See Order Expanding the Eastern Snake Plain Aquifer Area of Common Ground Water Supply to Include the Big Lost River Tributary Basin* (Jan. 13, 2026).

This order is necessary because the expansion of the ESPA ACGWS subjects previously unadministered ground water rights to administration in the SWC delivery call proceeding. Furthermore, there is currently a curtailment order in effect in the SWC delivery call proceeding, curtailing ground water rights junior to August 15, 1952. *See Final Order Curtailing Ground Water Rights Junior to August 15, 1952* (Dec. 8, 2025).

The Director must decide how to address the inclusion of these ground water rights into the ESPA ACGWS and decide whether the administration of the newly included junior-priority ground water rights should be phased-in pursuant to Rule 40.01.a of the Rules for Conjunctive Management of Surface and Ground Water Resources ("CM Rule") (IDAPA 37.03.11).

ANALYSIS

When the Director issued the orders expanding the ESPA ACGWS, 1,005 ground water rights within the expanded area of administration not previously subject to administration were brought into the SWC delivery call and immediately became subject to administration. These water rights are listed in Attachment A to this order.

As discussed above, there is currently a curtailment order in effect in the SWC delivery call proceeding, curtailing ground water rights junior to August 15, 1952. Many of the previously unadministered ground water rights are not currently participating in a Department-approved mitigation plan. Therefore, the newly included water rights junior to August 15, 1952, not currently participating in an approved mitigation plan are subject to immediate curtailment under the current curtailment order. CM Rule 40.

Pursuant to CM Rule 40.01.a, the Director may, by order, phase-in regulation of junior-priority ground water diversions where material injury is delayed or long range to lessen the economic impact of immediate and complete curtailment.

The Director finds that the material injury caused by the diversion and use of water under these newly included ground water rights is delayed or long range. The Director also finds that the economic impact of immediate and complete curtailment would be severe. The Department has observed that the time required to submit, review, publish, and issue an order regarding a mitigation plan can vary greatly. Approval of an unprotested mitigation plan can occur as quickly as several months. Whereas a protested mitigation plan that is subject to a contested case proceeding and appeal process can take more than a year to resolve.

The Director concludes that priority administration of these newly included ground water rights should be phased-in to provide the affected water users a reasonable time to implement a mitigation plan "to lessen the economic impact of immediate and complete curtailment." CM Rule 40.01.a. Accordingly, the newly included water rights listed in Attachment A will not be subject to administration in the SWC delivery call sooner than April 1, 2027. All water rights that are newly included in the ESPA ACGWS are on notice that they could be subject to a curtailment order in approximately 14 months.

ORDER

Based upon and consistent with the foregoing, IT IS HEREBY ORDERED that ground water rights newly included in the ESPA ACGWS and listed in Attachment A to this order will be phased-in to the SWC delivery call proceeding and will not be subject to administration sooner than April 1, 2027.

Dated this 2th day of February 2026.

MATHEW WEAVER
Director

EXPLANATORY INFORMATION TO ACCOMPANY A FINAL ORDER

(To be used in connection with actions when a hearing was **not** held)

(Required by Rule of Procedure 740.02)

The accompanying order is a "**Final Order**" issued by the department pursuant to section 67-5246, Idaho Code.

PETITION FOR RECONSIDERATION

Any party may file a petition for reconsideration of a final order within fourteen (14) days of the service date of this order as shown on the certificate of service. **Note: The petition must be received by the Department within this fourteen (14) day period.** The department will act on a petition for reconsideration within twenty-one (21) days of its receipt, or the petition will be considered denied by operation of law. See section 67-5246(4), Idaho Code.

REQUEST FOR HEARING

Unless the right to a hearing before the director or the water resource board is otherwise provided by statute, any person who is aggrieved by the action of the director, and who has not previously been afforded an opportunity for a hearing on the matter shall be entitled to a hearing before the director to contest the action. The person shall file with the director, within fifteen (15) days after receipt of written notice of the action issued by the director, or receipt of actual notice, a written petition stating the grounds for contesting the action by the director and requesting a hearing. See section 42-1701A(3), Idaho Code. **Note: The request must be received by the Department within this fifteen (15) day period.**

Revised June 28, 2024

BEFORE THE DEPARTMENT OF WATER RESOURCES

OF THE STATE OF IDAHO

IN THE MATTER OF DISTRIBUTION OF WATER TO VARIOUS WATER RIGHTS HELD BY OR FOR THE BENEFIT OF A&B IRRIGATION DISTRICT, AMERICAN FALLS RESERVOIR DISTRICT #2, BURLEY IRRIGATION DISTRICT, MILNER IRRIGATION DISTRICT, MINIDOKA IRRIGATION DISTRICT, NORTH SIDE CANAL COMPANY, AND TWIN FALLS CANAL COMPANY	Docket No. CM-DC-2010-001 **FINAL ORDER REGARDING APRIL 2026 FORECAST SUPPLY** **(METHODOLOGY STEPS 1–3)**

FINDINGS OF FACT

1. On July 19, 2023, the Idaho Department of Water Resources ("Department") issued its *Sixth Final Order Regarding Methodology for Determining Material Injury to Reasonable In-Season Demand and Reasonable Carryover* ("*Methodology Order*"). The *Methodology Order* established nine steps for determining material injury to members of the Surface Water Coalition ("SWC"). This order applies steps 1, 2, and 3 of the *Methodology Order*.[1]

A. Step 1

2. By April 1 of each year, Step 1 requires members of the SWC to submit to the Department electronic shapefiles delineating the total anticipated irrigated acres for the upcoming year "or confirm in writing that the existing electronic shape file submitted by SWC has not varied by more than five percent." *Methodology Order* ¶ 1, at 41.

3. On February 17, 2026, Minidoka Irrigation District ("Minidoka") submitted its electronic shapefile delineating its total irrigated acres to the Department.

4. On March 27, 2026, the Department received a letter from A&B Irrigation District ("A&B"), Burley Irrigation District ("BID"), Milner Irrigation District ("Milner"), North Side Canal Company ("NSCC"), and Twin Falls Canal Company ("TFCC"). In the letter, A&B, BID, Milner, and NSCC confirmed that their total number of irrigated acres for 2026 will not vary by more than five percent from the electronic shapefiles submitted in prior years. With the letter, TFCC submitted an electronic shapefile delineating its total irrigated acres.

[1] Shortly after the *Methodology Order* was issued, the City of Pocatello, the City of Idaho Falls, and the Coalition of Cities (collectively "Cities") and the Idaho Ground Water Appropriators, Inc. ("IGWA") filed petitions for judicial review in Ada County (Nos. CV01-23-13238 and CV01-23-13173). IGWA's petition for judicial review is stayed until December 31, 2027. The Idaho Supreme Court dismissed the Cities' petition for lack of jurisdiction, but the matter is still pending on a petition for rehearing. The filing of a petition for judicial review does not stay the effectiveness of an order. I.C. § 67-5274. No party to the judicial review proceedings has requested a stay of the *Methodology Order*. Accordingly, the Director will apply the *Methodology Order* in this order.

5. On April 8th, 2026, the Department received a letter from American Falls Reservoir District #2 ("AFRD2"), stating that its total number of irrigated acres has not varied by more than five percent.

6. Based on the information submitted by the SWC, the Department will use the following total irrigated acres:

	Total Irrigated Acres[2]	Data Source
A&B	14,749[3]	SRBA Partial Decree
AFRD2	62,361	SRBA Partial Decree
BID	46,035	2013 shapefile submitted by BID, reduced by the Department for overlapping acres and acres outside of service area.
Milner	13,264	2010 service area shapefile, reduced by the Department for overlapping acres and acres outside of service area.
Minidoka	73,825	2026 shapefile submitted by Minidoka, reduced by the Department for overlapping acres and acres outside of the service area.
NSCC	154,067	SRBA Partial Decree
TFCC	193,638	2026 shapefile submitted by TFCC, reduced by the Department for overlapping acres and acres outside of service area.[4]

B. Step 2

7. Step 2 states that, within fourteen days of the issuance of the joint forecast prepared by the United States Bureau of Reclamation ("USBR") and the United States Army Corps of Engineers ("USACE"), the Director "will issue a final order predicting the April [Forecast Supply] for the water year for each SWC entity. The Director will compare the April [Forecast Supply] for each SWC entity to the [Baseline Demand] for each SWC entity to determine if an in-season demand shortfall ("IDS") is anticipated for the upcoming irrigation season." *Methodology Order* ¶ 3, at 42.

[2] "The number of irrigated acres used in this methodology order is the number of reported acres unless that number is larger than the decreed irrigated acres, and if so, then the decreed acres are used." *Methodology Order* ¶ 22, at 11.

[3] The Department has modified the total A&B irrigated acreage count to 14,749 acres. Based on Judge Wildman's district court decision, the new acreage count removes A&B's enlargement acres. *Mem. Decision & Order*, at 8, *City of Idaho Falls v. Idaho Dep't of Water Res.*, No. CV01-23-13238 (Ada Cnty. Dist. Ct. Idaho May 31, 2024).

[4] On April 10, 2026, the Cities filed *Cities' Motion to Consider Information When Determining Surface Water Coalition's Irrigated Acres Under Methodology Step 1* ("*Motion*"). In that motion, they ask the Director to consider the information contained in a technical memorandum prepared by the Cities' consultants when determining TFCC's total irrigated acres in this order. *Motion*, at 2. The motion was filed only days before the deadline for this order, leaving the Department insufficient time to evaluate its merits. The Director may revisit, and if appropriate, modify TFCC's total irrigated acres in orders issued later this irrigation season.

8. On April 2, 2026, the USBR and USACE issued their joint forecast ("Joint Forecast"), predicting an unregulated inflow of 2,300,000 acre-feet at the Snake River near Heise gage for the period of April through July. The forecasted flow volume equates to 70% percent of the average.[5] The Joint Forecast "is generally as accurate a forecast as is possible using current data gathering and forecasting techniques." *Id.* ¶ 49, at 19 (citation omitted).

9. The April–July Heise natural flow data from the years 1990–2025 were data inputs for the development of regression equations for A&B and Milner to predict the natural flow supply.[6] Data greater or less than two standard deviations from the average were excluded from the regression development.

10. The April–July Heise natural flow data from the years 1990–2025 and Box Canyon November–March total discharge data for the period 1989–2025, were data inputs for the development of multiple linear regression equations to predict the natural flow supplies for AFRD2, BID, Minidoka, NSCC, and TFCC. *Methodology Order* ¶ 49, at 19. The U.S. Geological Survey measures and monitors the flow at the Box Canyon stream flow measurement gage. The Box Canyon November–March total discharge used by the Director in the 2026 regression models totaled 93,824 acre-feet.

11. The storage allocations were predicted for each SWC member. As of April 6, 2026, Water District No. 1's preliminary water right accounting indicates water rights for Jackson Lake 1906, Lake Walcott, Jackson Lake 1910, Palisades Winter Water Savings, Island Park 1921, American Falls Winter Water Savings, and Henrys Lake 1965 are satisfied. The remaining reservoir rights are 838,546 acre-feet short of satisfaction. Based on a comparison of the current Heise natural flow forecast to the analog years of 2002, 2004, 2013, and 2021, the Director anticipates the remaining reservoir water rights for Jackson Lake and Palisades will be 48-87% satisfied, and each SWC member will receive 90-100% of their allocation. The storage allocations are based on the anticipated allocations minus evaporation charges.

[5] The average is based on the years 1991–2020. The Joint Forecast relies on a "30-Year Climate Normal" to calculate an average April through July runoff volume.

[6] Attached hereto, as Attachment A, are the regression analyses for each SWC entity used to predict natural flow supply.

12. Based on the above, the Director projects the following shortfalls:

	Predicted Natural Flow Supply	Predicted Storage Allocation	Minidoka Credit Adjustment	Total Forecast Supply	Baseline Demand (BLY 2018)	In-Season Demand Shortfall
A&B	1,693	120,313		122,006	64,192	0
AFRD2	31,003	383,024	1,000	415,027	458,890	43,900
BID	72,555	217,257	5,130	294,942	262,211	0
Milner	4,568	79,513		84,081	58,417	0
Minidoka	98,553	341,646	8,370	448,569	354,851	0
NSCC	279,289	821,048	-7,750	1,092,587	1,026,661	0
TFCC	757,715	233,029	-6,750	983,994	1,121,717	137,700
				Total Predicted April In-Season Demand Shortfall (AF)		181,600

C. Step 3

13. Step 3 requires the following:

> Step 3: By May 1, or within fourteen (14) days from issuance of the final order predicting the April [Forecast Supply], whichever is later in time, junior ground water users with approved mitigation plans for delivery of water must secure, to the satisfaction of the Director, a volume of water equal to their proportionate share of the April IDS unless the April IDS is revised as explained below in paragraph 6. If junior ground water users secured water for a reasonable carryover shortfall to an individual SWC member in the previous year, the current-year mitigation obligation to the individual SWC member will be reduced by the quantity of water secured for the reasonable carryover shortfall. The secured water will not be required to be delivered to the injured members of the SWC until the Time of Need.

Methodology Order ¶ 4, at 42.

14. The predicted April IDS for AFRD2 is 43,900 acre-feet and TFCC is 137,700 acre-feet. The total predicted April IDS is 181,600 acre-feet.

15. The Eastern Snake Plain Aquifer Model ("ESPAM") is used to predict the junior priority water rights that must be curtailed to produce the volume of water equal to the predicted April IDS in the near Blackfoot to Minidoka reach. The ESPAM is updated periodically as new field measurements and advancements in modeling technology become available. ESPAM Version 2.2 ("ESPAM2.2") is the latest model version.[7]

[7] The Department finalized ESPAM2.2 model documentation reports (including a model calibration report, a predictive uncertainty analysis, a superposition model scenario, and a curtailment scenario) on May 27, 2021. *See* Idaho Dep't of Water Res., *ESPAM2.2 Reports* (2021), https:// research.idwr.idaho.gov/files/projects/espam/browse/ESPAM22_Reports/.

16. The Department ran ESPAM2.2 to predict the junior priority water rights within the area of common ground water supply ("ACGWS") that must be curtailed to produce the volume of water equal to the predicted April IDS between May 1 and September 30 of this irrigation season pursuant to the *Methodology Order*. The ESPAM2.2 simulation calculated the curtailment of ground water rights bearing priority dates junior to October 11, 1900, will produce a volume of water of 94,000 acre-feet in the near Blackfoot to Minidoka reach between May 1 and September 30 of this irrigation season. The predicted benefit of the curtailment is less than the April IDS of 181,600 acre-feet. Curtailing ground water rights bearing priority dates junior to October 11, 1900, will offset as much of the April IDS as possible.

CONCLUSIONS OF LAW

1. The Fifth Judicial District Court, in and for the County of Minidoka, held that the evidentiary standard of proof to apply in conjunctive administration of hydraulically connected water rights is clear and convincing. *See Mem. Decision & Order on Pets. for Jud. Rev.*, *A&B Irr. Dist., Inc. v. Idaho Dep't of Water Res.*, No. CV-2009-647 (Minidoka Cnty. Dist. Ct. Idaho May 4, 2010); *Mem. Decision & Order on Pets. for Reh'g*, *A&B Irr. Dist., Inc. v. Idaho Dep't of Water Res.*, No. CV-2009-647 (Minidoka Cnty. Dist. Ct. Idaho Nov. 2, 2010).

2. "Clear and convincing evidence refers to a degree of proof greater than a mere preponderance." *Idaho State Bar v. Topp*, 129 Idaho 414, 416, 925 P.2d 1113, 1115 (1996) (internal quotations omitted). "Clear and convincing evidence is generally understood to be '[e]vidence indicating that the thing to be proved is highly probable or reasonably certain.'" *State v. Kimball*, 145 Idaho 542, 546, 181 P.3d 468, 472 (2008) (citing *In re Adoption of Doe*, 143 Idaho 188, 191, 141 P.3d 1057, 1060 (2006)); *see also Idaho Dep't of Health & Welfare v. Doe*, 150 Idaho 36, 41, 244 P.3d 180, 185 (2010).

3. The Director must utilize the best available technology for determining the impact of junior ground water diversions. *See Clear Springs Foods, Inc. v. Spackman*, 150 Idaho 790, 814, 252 P.3d 71, 95 (2011). ESPAM 1.1 and 2.1 are the model versions utilized previously in the SWC delivery call proceedings. Previously, the Director determined that ESPAM 2.1 was the best available scientific tool for predicting the effects of ground water pumping. *See Idaho Ground Water Assoc. v. Idaho Dep't of Water Res.*, 160 Idaho 119, 124, 369 P.3d 897, 902 (2016). ESPAM 2.2 is the latest version of the ESPAM model. The improvements incorporated into ESPAM 2.2, as discussed in Finding of Fact 15, make it the best available scientific tool for predicting the effects of ground water pumping in this proceeding.

4. In 2026, the Director has sufficient information to quantify the irrigated areas for each of the SWC members as required by Step 1.

5. The USBR-USACE April Joint Forecast predicts an unregulated inflow of 2,300,000 acre-feet at the Snake River near Heise gage from April to July. The forecasted volume equates to 70% of the average.

6. The predicted April IDS is 181,600 acre-feet. Junior ground water users holding consumptive water rights bearing priority dates junior to October 11, 1900, within the Eastern Snake Plain Aquifer ACGWS must mitigate for their proportionate share of the predicted April IDS in accordance with an approved mitigation plan.[8] Junior ground water users mitigating for their proportionate share of the predicted April IDS with a secured volume of water pursuant to an approved mitigation plan must, to the satisfaction of the Director, secure their proportionate share for delivery to the injured members of the SWC on or before May 1, 2026. There was a reasonable carryover shortfall of 86,756 acre-feet in the fall of 2025. However, because junior ground water users did not secure any mitigation water for a carryover shortfall, there is no adjustment to the mitigation obligation.

7. If, on or before May 1, 2026, ground water users holding consumptive water rights bearing priority dates junior to October 11, 1900, within the Eastern Snake Plain Aquifer ACGWS[9] fail to establish, to the satisfaction of the Director, that they can mitigate for their proportionate share of the predicted April IDS of 181,600 acre-feet in accordance with an approved mitigation plan, the Director will issue an order curtailing the junior-priority ground water user. Junior ground water users who are mitigating with a secured volume of water are not required to assign the secured volume of water until after the Director issues a subsequent order requiring the assignment of the water.

8. If, at any time prior to the Director's final determination of the April Forecast Supply, the Director can determine with certainty that any member of the SWC has diverted more natural flow than predicted, or has accrued more storage than predicted, the Director will revise his initial, predicted IDS determination.

---

[8] There are five approved mitigation plans responding to the SWC delivery call, each is stipulated to by the SWC: (1) No. CM-MP-2015-003 for the benefit of A&B; (2) No. CM-MP-2010-001 for the benefit of Southwest Irrigation District and Goose Creek Irrigation District (collectively, "SWID"); (3) No. CM-MP-2024-003 for the benefit of the Ground Water Districts; (4) No. CM-MP-2019-001 for the benefit of the Coalition of Cities; and (5) No. CM-MP-2007-001 for the benefit of the Water Mitigation Coalition. Given the nature of certain plans, the Department must calculate the proportionate share of the predicted IDS. With regard to A&B's mitigation plan, A&B's proportionate share of the predicted April IDS of 181,600 acre-feet is 10,800 acre-feet. Due to the nature of the mitigation plans for SWID, the Ground Water Districts, the Coalition of Cities, and the Water Mitigation Coalition, these entities do not need to establish that they can mitigate for their proportionate share of the predicted IDS.

[9] On June 28, 2024, the Director issued an order declaring that ground water rights that were to be newly included in the ESPA ACGWS starting July 1, 2024, due to the passage of Senate Bill 1341, would not be subject to administration until November 1, 2025. *Order Re. Mid-Season Change to Area of Common Ground Water Supply for E. Snake Plain Aquifer; 3d Order Am. Curtailment List*, at 4; *see* S.B. 1341, 67th Leg., 2d Reg. Sess. (Idaho 2024) (enacted as I.C. § 42-233c). Accordingly, ground water users holding consumptive water rights bearing priority dates junior to October 11, 1900, that were included in the ESPA ACGWS due to the passage of Senate Bill 1341 are subject to administration at this time continuing indefinitely into the future and are required to establish that they can mitigate for their proportionate share of the predicted April IDS. In late 2025 and early 2026, the Director expanded the ESPA ACGWS to include the Raft River tributary basin and the remainder of the Little Lost River and Big Lost River tributary basins not already included in the ACGWS. On February 2, 2026, the Director issued an order declaring that ground water users included in the ESPA ACGWS in late 2025 and early 2026 would not be subject to administration before April 1, 2027. *Order Phasing in Administration of Ground Water Rights Recently Included in the ESPA ACGWS*, at 2. Accordingly, at this time, ground water users in the Raft River tributary basin and the remainder of the Little Lost River and Big Lost River tributary basins who were newly included into the ESPA ACGWS and hold consumptive water rights bearing priority dates junior to October 11, 1900, are not subject to administration.

ORDER

Based upon and consistent with the foregoing, IT IS HEREBY ORDERED as follows:

The Director predicts an April IDS of 181,600 acre-feet. On or before May 1, 2026, ground water users holding consumptive water rights bearing priority dates junior to October 11, 1900, within the Eastern Snake Plain Aquifer ACGWS shall establish, to the satisfaction of the Director, that they can mitigate for their proportionate share of the predicted April IDS of 181,600 acre-feet in accordance with an approved mitigation plan. If a junior ground water user cannot establish, to the satisfaction of the Director, that they can mitigate for their proportionate share of the predicted April IDS in accordance with an approved mitigation plan, the Director will issue an order curtailing the junior-priority ground water user.

Dated this 16th day of April 2026.

MATHEW WEAVER
Director

EXPLANATORY INFORMATION TO ACCOMPANY A FINAL ORDER

(To be used in connection with actions when a hearing was **not** held)

The accompanying document is a "**Final Order"** issued by the Idaho Department of Water Resources ("Department") pursuant to Idaho Code § 67-5246. The following statements describe the procedures and time limits for seeking reconsideration or other administrative relief as required by Idaho Code § 67-5248.

PETITION FOR RECONSIDERATION

(*See* Idaho Code § 67-5246(4))

Any party may file a petition for reconsideration of this final order within fourteen (14) days of the service date of this order as shown on the certificate of service. **Note: the petition must be received by the Department within this fourteen (14) day period.** The presiding officer will act on a petition for reconsideration within twenty-one (21) days of its receipt, or the petition will be considered denied by operation of law.

REQUEST FOR HEARING

(*See* Idaho Code § 42-1701A(3))

Unless the right to a hearing before the Director or the Water Resource Board is otherwise provided by statute, any person aggrieved by any final decision, determination, order, or action of the Director of the Department and who has not previously been afforded an opportunity for a hearing on the matter shall be entitled to a hearing before the Director to contest the action. The person shall file with the Director, within fifteen (15) days after receipt of written notice of the action issued by the Director, or receipt of actual notice, a written petition stating the grounds for contesting the action by the Director and requesting a hearing. **Note: The request must be received by the Department within this fifteen (15) day period.**

CERTIFICATE OF SERVICE

(*See* IDAPA 37.01.01.053, 37.01.01.202)

All documents filed with the Department in connection with a petition for reconsideration or a request for hearing of this final order shall be served on all other parties to the proceeding in accordance with Rules 53 and 202 of the Department's Rules of Procedure.

BEFORE THE DEPARTMENT OF WATER RESOURCES

OF THE STATE OF IDAHO

IN THE MATTER OF DISTRIBUTION OF WATER TO VARIOUS WATER RIGHTS HELD BY OR FOR THE BENEFIT OF A&B IRRIGATION DISTRICT, AMERICAN FALLS RESERVOIR DISTRICT #2, BURLEY IRRIGATION DISTRICT, MILNER IRRIGATION DISTRICT, MINIDOKA IRRIGATION DISTRICT, NORTH SIDE CANAL COMPANY, AND TWIN FALLS CANAL COMPANY	Docket No. CM-DC-2010-001 **FINAL ORDER CURTAILING GROUND WATER RIGHTS JUNIOR TO OCTOBER 11, 1900**

The Director of the Idaho Department of Water Resources ("Department") finds, concludes, and orders as follows:

FINDINGS OF FACT

1. On July 19, 2023, the Director issued the *Sixth Final Order Regarding Methodology for Determining Material Injury to Reasonable In-Season Demand and Reasonable Carryover* ("*Methodology Order*").[1] The *Methodology Order* established nine steps for determining material injury to members of the Surface Water Coalition ("SWC").[2]

2. On April 16, 2026, the Director issued the *Final Order Regarding April 2026 Forecast Supply (Methodology Steps 1–3)* ("*As-Applied Order*"), which applied steps 1, 2, and 3 of the *Methodology Order*. The Director predicted an April in-season demand shortfall ("IDS") of 181,600 acre-feet. *As-Applied Order*, at 4. The Director ordered that, by May 1, 2026, ground water users with consumptive water rights "bearing priority dates junior to October 11, 1900, within the Eastern Snake Plain Aquifer area of common ground water supply [("ESPA ACGWS")] shall establish, to the satisfaction of the Director, that they can mitigate for their proportionate share of the predicted April IDS of 181,600 acre-feet in accordance with an approved mitigation plan." *Id.* at 6. The Director also ordered that, if such a junior ground water user cannot establish that they can mitigate for their proportionate share of the predicted IDS "in accordance with an approved mitigation plan, the Director will issue an order curtailing the junior-priority ground water user." *Id.*

[1] Shortly after the *Methodology Order* was issued, the City of Pocatello, the City of Idaho Falls, and the Coalition of Cities (collectively "Cities") and the Idaho Ground Water Appropriators, Inc. ("IGWA") filed petitions for judicial review in Ada County (Nos. CV01-23-13238 and CV01-23-13173). IGWA's petition for judicial review is stayed until December 31, 2027. The Idaho Supreme Court dismissed the Cities' petition for lack of jurisdiction. The filing of a petition for judicial review does not stay the effectiveness of an order. I.C. § 67-5274. No party to the judicial review proceedings has requested a stay of the *Methodology Order*. Accordingly, the Director will apply the *Methodology Order* in this order.

[2] The SWC is comprised of A&B Irrigation District, American Falls Reservoir District #2, Burley Irrigation District, Milner Irrigation District, Minidoka Irrigation District, North Side Canal Company, and Twin Falls Canal Company.

3. Prior to May 1, 2026, there were five approved mitigation plans in place responding to the SWC delivery call, each is stipulated to by the SWC:

(1) Docket No. CM-MP-2010-001 for the benefit of the Southwest Irrigation District and Goose Creek Irrigation District (collectively, "SWID");

(2) Docket No. CM-MP-2019-001 for the benefit of certain cities commonly referred to as the "Coalition of Cities";

(3) Docket No. CM-MP-2015-003 for the benefit of the A&B Irrigation District ("A&B");

(4) Docket No. CM-MP-2007-001 for the benefit of certain entities commonly referred to as the "Water Mitigation Coalition"; and

(5) Docket No. CM-MP-2024-003 for the benefit of certain ground water districts commonly referred to as the "Ground Water Districts."

4. In the 2026 *As-Applied Order*, the Director found that due to the nature of the approved mitigation plans for SWID, the Coalition of Cities, the Water Mitigation Coalition and the Ground Water Districts, these entities do not need to establish they can mitigate for their proportionate share of the predicted April IDS. *As-Applied Order*, at 6 n.8. However, the Director found that A&B must mitigate for its proportionate share of the predicted IDS of 181,600 acre-feet and determined that A&B's proportionate share is 10,800 acre-feet. *Id*.

5. On May 1, 2026, A&B, the other members of the SWC, IGWA, and American Falls-Aberdeen Ground Water District filed a *Joint Motion for Order Approving Amended 2026-2027 Interim Stipulation* ("*Amended Joint Motion*") requesting approval of A&B's previously filed *Interim Stipulation* with an amendment to the storage volume of water to be delivered. *Amended Joint Motion*, at 3, No. CM-MP-2026-003. On May 14, 2026, the Director issued an *Order Approving A&B Irrigation District's Interim Stipulated Plan for 2026 & 2027*. Due to the nature of A&B's new mitigation plan, it does not need to mitigate for its full proportional share of the predicted IDS.

6. Also on May 1, 2026, the SWC, the Ground Water Districts, the Big Lost River Ground Water District, the Upper Big Lost River Ground Water District, and the Little Lost River Ground Water District filed a *Joint Motion for Approval of First Addendum to 2024 Stipulated Mitigation Plan and for Related Relief* ("*Motion to Approve First Addendum*"). The *Motion to Approve First Addendum* requested the Director approve the First Addendum, which allows the Big Lost River Ground Water District, Upper Big Lost River Ground Water District, and Little Lost River Ground Water District to join the *2024 Stipulated Mitigation Plan* in No. CM-MP-2024-003. On May 7, 2026, the Director issued an *Order Approving First Addendum and Granting Related Relief*.

7. Also on May 1, 2026, Hearing Officer Gerald Schroeder issued a *Preliminary Order Approving Falls Water's Stipulated Mitigation Plan* in Department Docket No. CM-MP-2026-

002. A petition for reconsideration is pending so the order has not become final yet pursuant to Idaho Code § 67-5245 and IDAPA 37.01.01.730.

CONCLUSIONS OF LAW

1. Idaho Code § 42-602 authorizes the Director to supervise water distribution within water districts:

> The director of the department of water resources shall have direction and control of the distribution of water from all natural water sources within a water district to the canals, ditches, pumps and other facilities diverting therefrom. Distribution of water within water districts created pursuant to section 42-604, Idaho Code, shall be accomplished by watermasters as provided in this chapter and supervised by the director. The director of the department of water resources shall distribute water in water districts in accordance with the prior appropriation doctrine. The provisions of chapter 6, title 42, Idaho Code, shall apply only to distribution of water within a water district.

2. As explained above, by May 1, 2026, ground water users with consumptive water rights "junior to October 11, 1900, within the [ESPA ACGWS]" are required to "establish, to the satisfaction of the Director, that they can mitigate for their proportionate share of the predicted April IDS of 181,600 acre-feet in accordance with an approved mitigation plan." *As-Applied Order*, at 7. If a junior ground water user does not establish that they can mitigate for their proportionate share of the predicted April IDS "in accordance with an approved mitigation plan" the ground water user will be subject to this "order curtailing the junior-priority ground water user." *Id.*

3. Due to the nature of the approved mitigation plans for SWID, the Coalition of Cities, the Water Mitigation Coalition, A&B, and the Ground Water Districts, these entities do not need to establish that they can mitigate for their proportionate share of the predicted April IDS. Junior ground water users entitled to the protection of SWID, the Coalition of Cities, the Water Mitigation Coalition, A&B, and the Ground Water Districts mitigation plans will not be subject to curtailment during the 2026 irrigation season.

4. Consistent with the *As-Applied Orde*r, Idaho Code § 42-602, and decisions of the courts, the Director must order curtailment of junior-priority ground water users that have not established they can mitigate in accordance with an approved mitigation plan. Junior-priority ground water users subject to curtailment are listed in Attachments A to this order.

ORDER

Based upon and consistent with the foregoing, IT IS HEREBY ORDERED that effective May 14, 2026, ground water users holding water rights bearing priority dates junior to October 11, 1900, within the ESPA ACGWS, and listed in Attachment A to this order, shall curtail/refrain from diversion and use of ground water pursuant to those water rights unless notified by the Department that the order of curtailment has been modified or rescinded as to their water rights.

IT IS FURTHER ORDERED that holders of ground water rights identified by the highlighted rows in Attachment A to this order may seek to participate in an approved mitigation plan through a ground water district and shall have fifteen days from the date of this order to join, solely for mitigation purposes, the ground water district situated nearest the lands to which the water rights are appurtenant. *See* H.B. 737a, 58th Leg., 2d Reg. Sess. (Idaho 2006) (*Act Relating to the Administration of Ground Water Rights Within the Eastern Snake River Plain*); *see also* I.C. § 42-5259.

IT IS FURTHER ORDERED that watermasters for the water districts within the ESPA ACGWS who regulate ground water are directed to review the water rights listed in Attachment A to this order and begin the curtailment process.

IT IS FURTHER ORDERED that this order shall apply to consumptive ground water rights, including but not limited to, agricultural, commercial, industrial, and municipal uses. This order excludes ground water rights used for *de minimis* domestic purposes where such domestic use is within the limits of the definition set forth in Idaho Code § 42-111 and ground water rights used for *de minimis* stock watering where such stock watering use is within the limits of the definitions set forth in Idaho Code § 42-1401A(11), pursuant to IDAPA 37.03.11.020.11.

Dated this 14th day of May 2026.

MATHEW WEAVER
Director

EXPLANATORY INFORMATION TO ACCOMPANY A FINAL ORDER

(To be used in connection with actions when a hearing was **not** held)

The accompanying document is a "**Final Order"** issued by the Idaho Department of Water Resources ("Department") pursuant to Idaho Code § 67-5246. The following statements describe the procedures and time limits for seeking reconsideration or other administrative relief as required by Idaho Code § 67-5248.

PETITION FOR RECONSIDERATION

(*See* Idaho Code § 67-5246(4))

Any party may file a petition for reconsideration of this final order within fourteen (14) days of the service date of this order as shown on the certificate of service. **Note: the petition must be received by the Department within this fourteen (14) day period.** The presiding officer will act on a petition for reconsideration within twenty-one (21) days of its receipt, or the petition will be considered denied by operation of law.

REQUEST FOR HEARING

(*See* Idaho Code § 42-1701A(3))

Unless the right to a hearing before the Director or the Water Resource Board is otherwise provided by statute, any person aggrieved by any final decision, determination, order, or action of the Director of the Department and who has not previously been afforded an opportunity for a hearing on the matter shall be entitled to a hearing before the Director to contest the action. The person shall file with the Director, within fifteen (15) days after receipt of written notice of the action issued by the Director, or receipt of actual notice, a written petition stating the grounds for contesting the action by the Director and requesting a hearing. **Note: The request must be received by the Department within this fifteen (15) day period.**

CERTIFICATE OF SERVICE

(*See* IDAPA 37.01.01.053, 37.01.01.202)

All documents filed with the Department in connection with a petition for reconsideration or a request for hearing of this final order shall be served on all other parties to the proceeding in accordance with Rules 53 and 202 of the Department's Rules of Procedure.

BEFORE THE DEPARTMENT OF WATER RESOURCES

OF THE STATE OF IDAHO

IN THE MATTER OF DISTRIBUTION OF WATER TO VARIOUS WATER RIGHTS HELD BY OR FOR THE BENEFIT OF A&B IRRIGATION DISTRICT, AMERICAN FALLS RESERVOIR DISTRICT #2, BURLEY IRRIGATION DISTRICT, MILNER IRRIGATION DISTRICT, MINIDOKA IRRIGATION DISTRICT, NORTH SIDE CANAL COMPANY, AND TWIN FALLS CANAL COMPANY	Docket No. CM-DC-2010-001 **ORDER AMENDING CURTAILMENT LIST TO INCLUDE UNMITIGATED GROUND WATER RIGHTS**

BACKGROUND

On April 16, 2026, the Director issued the *Final Order Regarding April 2026 Forecast Supply (Methodology Steps 1–3)* ("*As-Applied Order*"), which applied steps 1, 2, and 3 of the *Sixth Final Order Regarding Methodology for Determining Material Injury to Reasonable In-Season Demand and Reasonable Carryover* ("*Methodology Order*"). The Director predicted an April in-season demand shortfall ("IDS") of 181,600 acre-feet. *As-Applied Order*, at 4. The Director ordered that, by May 1, 2026, ground water users with consumptive water rights "bearing priority dates junior to October 11, 1900, within the Eastern Snake Plain Aquifer area of common ground water supply [("ESPA ACGWS")] shall establish, to the satisfaction of the Director, that they can mitigate for their proportionate share of the predicted April IDS of 181,600 acre-feet in accordance with an approved mitigation plan." *Id.* at 6. The Director also ordered that, if such a junior ground water user cannot establish that they can mitigate for their proportionate share of the predicted IDS "in accordance with an approved mitigation plan, the Director will issue an order curtailing the junior-priority ground water user." *Id.*

On May 14, 2026, the Director issued a *Final Order Curtailing Ground Water Rights Junior to October 11, 1900* ("*May Curtailment Order*"). The *May Curtailment Order* required holders of ground water rights within the ESPA ACGWS bearing priority dates junior to October 11, 1900, and listed in Attachment A, to "curtail/refrain from diversion and use of ground water pursuant to those water rights unless notified by the Department that the order of curtailment has been modified or rescinded as to their water rights." *May Curtailment Order*, at 3.

Attachment A excluded certain junior-priority ground water rights bearing a priority date junior to October 11, 1900, that the Department understood to be protected by an approved mitigation plan. Following issuance of the *May Curtailment Order*, the Director became aware of several ground water rights bearing priority dates junior to October 11, 1900, that were not in fact covered by an approved mitigation plan and were incorrectly omitted from on Attachment A to the *May Curtailment Order*.

ANALYSIS

Idaho Code § 42-602 authorizes the Director to supervise water distribution within water districts:

> The director of the department of water resources shall have direction and control of the distribution of water from all natural water sources within a water district to the canals, ditches, pumps and other facilities diverting therefrom. Distribution of water within water districts created pursuant to section 42-604, Idaho Code, shall be accomplished by watermasters as provided in this chapter and supervised by the director. The director of the department of water resources shall distribute water in water districts in accordance with the prior appropriation doctrine. The provisions of chapter 6, title 42, Idaho Code, shall apply only to distribution of water within a water district.

"[W]hen it is found that junior-priority ground water pumping is causing a senior right holder material injury, the Director must either: (1) curtail junior-priority ground water pumping to satisfy the senior's right, or (2) '[a]llow out-of-priority diversion of water by junior-priority ground water users pursuant to a mitigation plan that has been approved by the Director.'" *Rangen, Inc. v. Idaho Dep't of Water Res.*, 160 Idaho 251, 256, 371 P.3d 305, 310 (2016), *abrogated in part on other ground by 3G AG LLC v. IDWR*, 170 Idaho 251, 509 P.3d 1180 (2022) (quoting IDAPA 37.03.040.01).

Consistent with the *As-Applied Orde*r, Idaho Code § 42-602, IDAPA 37.03.040.01, and decisions of the courts, the Director must order curtailment of junior-priority ground water users that have not established they can mitigate in accordance with an approved mitigation plan. Thus, the curtailment list must be supplemented to include those unmitigated junior-priority ground water rights that were not included in Attachment A to the *May Curtailment Order*.

ORDER

Based upon and consistent with the foregoing, IT IS HEREBY ORDERED that effective June 17, 2026, the curtailment list is amended to include the following ground water rights:

Water Right No. 25-7540, Laura Lee Hobbs, Licensed, Priority Date 08/18/1989, 0.10 cfs.

Water Right No. 25-4103, Bill Vaughn, Decreed, Priority Date 12/31/1958, 0.11 cfs.

Water Right No. 35-14613, Western Slope LLC., Decreed, Priority Date 03/05/1948, 0.61 cfs.

Water Right No. 35-14615, Western Slope LLC., Decreed, Priority Date 12/31/1940, 0.88 cfs.

Water Right No. 35-14617, Western Slope LLC., Decreed, Priority Date 09/28/1981, 0.05 cfs.

Water Right No. 35-7576, Woodland Heights Water Users Association., Decreed, 01/28/1976, 0.38 cfs.

IT IS FURTHER ORDERED that holders of these ground water rights shall immediately curtail/refrain from diversion and use of ground water pursuant to these water rights unless notified by the Department that the order of curtailment has been modified or rescinded as to their water rights. All other ground water rights listed in the Attachment A continue to be curtailed consistent with the *Final Order Curtailing Ground Water Rights Junior to October 11, 1900.*

Dated this 17th day of June 2026

MATHEW WEAVER
Director

CERTIFICATE OF SERVICE

I HEREBY CERTIFY that on this 17th day of June 2026, the above and foregoing, was served by the method indicated below, and addressed to the following:

BEFORE THE DEPARTMENT OF WATER RESOURCES

OF THE STATE OF IDAHO

IN THE MATTER OF DISTRIBUTION OF WATER TO VARIOUS WATER RIGHTS HELD BY OR FOR THE BENEFIT OF A&B IRRIGATION DISTRICT, AMERICAN FALLS RESERVOIR DISTRICT #2, BURLEY IRRIGATION DISTRICT, MILNER IRRIGATION DISTRICT, MINIDOKA IRRIGATION DISTRICT, NORTH SIDE CANAL COMPANY, AND TWIN FALLS CANAL COMPANY	Docket No. CM-DC-2010-001 **ORDER REVISING APRIL 2026 FORECAST SUPPLY AND CONTINUING MAY 14, 2026 CURTAILMENT ORDER** ***(METHODOLOGY STEPS 5 & 6)***

The Director of the Idaho Department of Water Resources ("Department") finds, concludes, and orders as follows:

FINDINGS OF FACT

A. Background

1. On July 19, 2023, the Department issued its *Sixth Final Order Regarding Methodology for Determining Material Injury to Reasonable In-Season Demand and Reasonable Carryover* ("*Methodology Order*"). The *Methodology Order* established nine steps for determining material injury to members of the Surface Water Coalition ("SWC"). This order applies Steps 5 and 6 of the *Methodology Order*.

2. Step 5 of the *Methodology Order* addresses the final injury determination to reasonable carryover for members of the SWC. Step 5 states:

> If the storage allocations held by members of the SWC fill, there is no reasonable carryover shortfall. If the storage allocations held by members of the SWC do not fill, within fourteen (14) days following the publication of Water District 01's initial storage report . . . the volume of water secured by junior ground water users to fulfill the reasonable carryover shortfall shall be made available to injured members of the SWC.

Methodology Order, at 43. On November 21, 2025, the Director issued the *Final Order Establishing 2025 Reasonable Carryover* (*Methodology Step 9*) ("*2025 Step 9 Order*") establishing a reasonable carryover shortfall of 86,756 acre-feet. Junior ground water users were given 14 days to provide a volume of water to fulfill the carryover shortfall. No water users secured water. While the SWC's storage allocation did not fill this year, because no water users secured water in 2025 to fulfill the carryover shortfall, there is no volume of water to be made available to the SWC under Step 5.

3. Step 6 of the *Methodology Order* states:

> Approximately halfway through the irrigation season, but following the events described in Step 5, the Director will, for each member of the SWC: (1) recalculate RISD [Reasonable In-Season Demand]; (2) issue a revised FS [Forecast Supply]; and (3) estimate the Time of Need date.

Methodology Order, at 43 (footnote omitted).

4. On April 16, 2026, the Director issued his *Final Order Regarding April 2026 Forecast Supply (Methodology Steps 1 – 3)* ("*April Forecast Supply Order*"). The *April Forecast Supply Order* predicted a demand shortfall to the SWC of 181,600 acre-feet for the 2026 irrigation season. *April Forecast Supply Order*, at 4. At that time, the members of the SWC predicted to experience material injury during the 2026 irrigation season were Twin Falls Canal Company ("TFCC") and American Falls Reservoir District #2 (AFRD2). *Id.* The Director ordered that, on or before May 1, 2026, ground water users with consumptive water rights "junior to October 11, 1900, within the Eastern Snake Plain Aquifer ACGWS [area of common ground water supply] shall establish, to the satisfaction of the Director, that they can mitigate for their proportionate share of the predicted April IDS [in-season demand shortfall] of 181,600 acre-feet in accordance with an approved mitigation plan." *Id.* at 7. The Director also ordered that, "[i]f a junior ground water user cannot establish . . . that they can mitigate for their proportionate share of the predicted April IDS in accordance with an approved mitigation plan, the Director will issue an order curtailing the junior-priority ground water user." *Id.*

5. On May 14, 2026, the Director issued a *Final Order Curtailing Ground Water Rights Junior to October 11, 1900* ("*Curtailment Order*"). The Director ordered that:

> [E]ffective May 14, 2026, ground water users holding water rights bearing priority dates junior to October 11, 1900, within the ESPA ACGWS, and listed in Attachment A to this order, shall curtail/refrain from diversion and use of ground water pursuant to those water rights unless notified by the Department that the order of curtailment has been modified or rescinded as to their water rights.

Curtailment Order, at 3.

6. On June 17, 2026, the Director issued an *Order Amending Curtailment List to Include Unmitigated Ground Water Rights*, adding six water rights to the list of water rights subject to the *Curtailment Order*.

B. April through June Water Supply Conditions and Climate

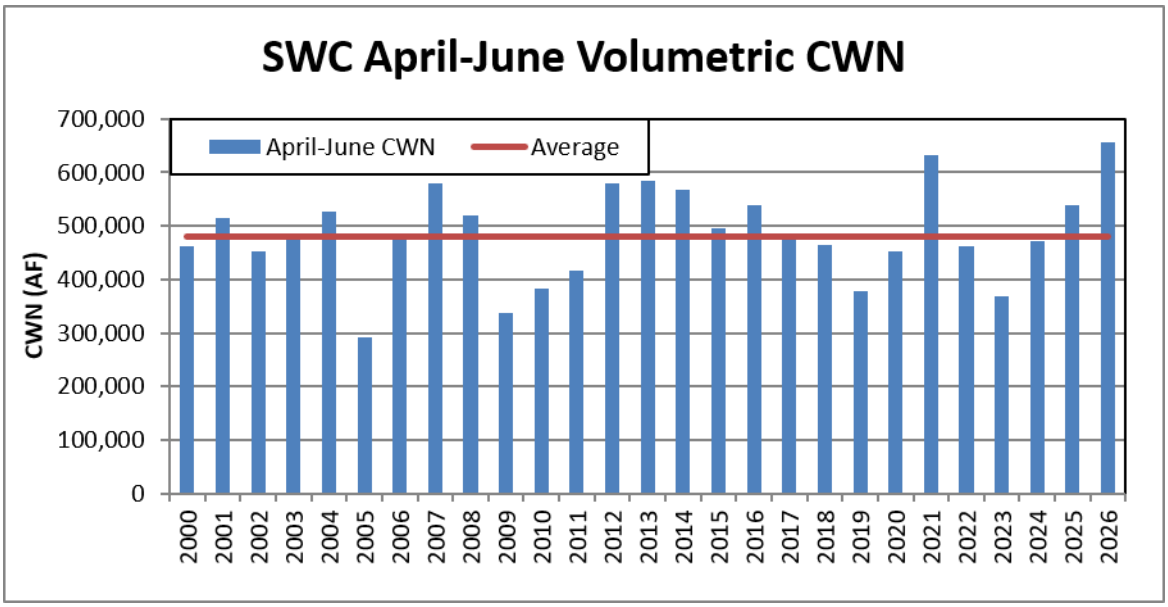
7. The April 2026 Joint Forecast prepared by the United States Army Corps of Engineers ("USACE") and the United States Bureau of Reclamation ("BOR") predicted 2,300,000 acre-feet of unregulated inflow at the Snake River near Heise gage for the period April–July 2025, which equates to 70% of the 1991–2020 average. *April Forecast Supply Order*,

at 2. The Joint Forecast "is generally as accurate a forecast as is possible using current data gathering and forecasting techniques." *Methodology Order*, at 19.

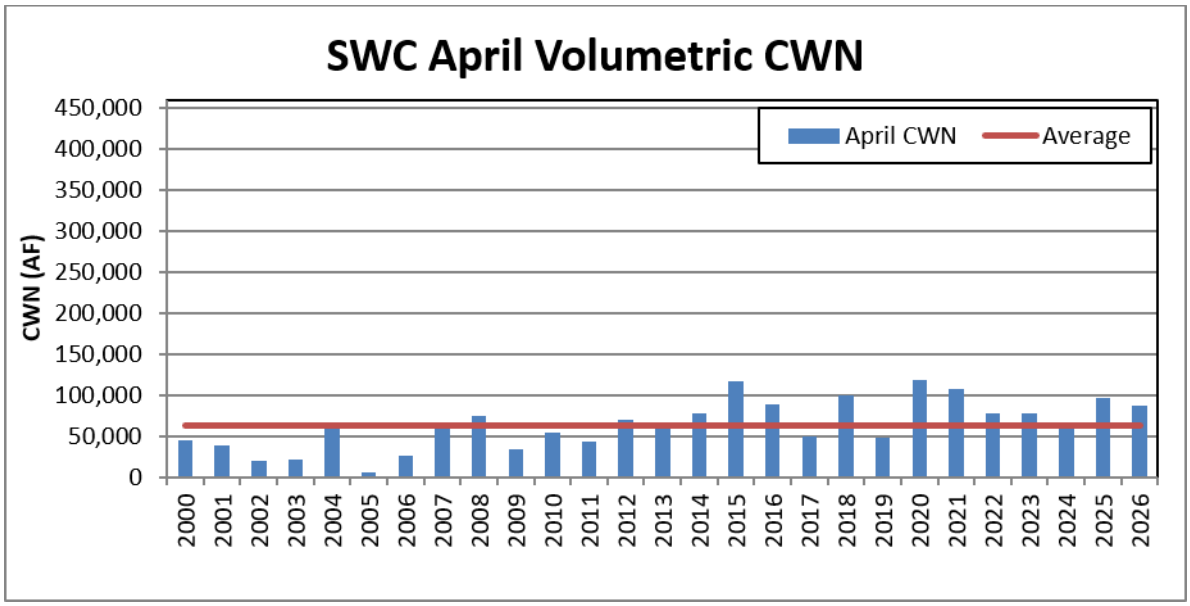
8. The June 2026 Joint Forecast prepared by the USACE and the BOR predicted 900,000 acre-feet of unregulated inflow at the Snake River near Heise gage for the period June–July 2025, which equates to 50% of the 1991–2020 average.

9. Over much of the Eastern Snake Plain and its tributary basins, precipitation was above average in April but below average in May and June. For example, according to data measured at all the Natural Resources Conservation Service's SNOTEL sites in the Upper Snake River Basin, the basin received 110%, 55%, and 63% of average precipitation in April, May, and June, respectively. Similarly, the National Weather Service's Twin Falls weather station reported 123%, 4%, and 53% of normal precipitation in April, May, and June, respectively. During the same time, temperatures were above average April through June. For example, the average daily temperatures reported by the National Weather Service's Twin Falls weather station were 1.7, 4.4, and 1.6 degrees above normal for April, May, and June, respectively.

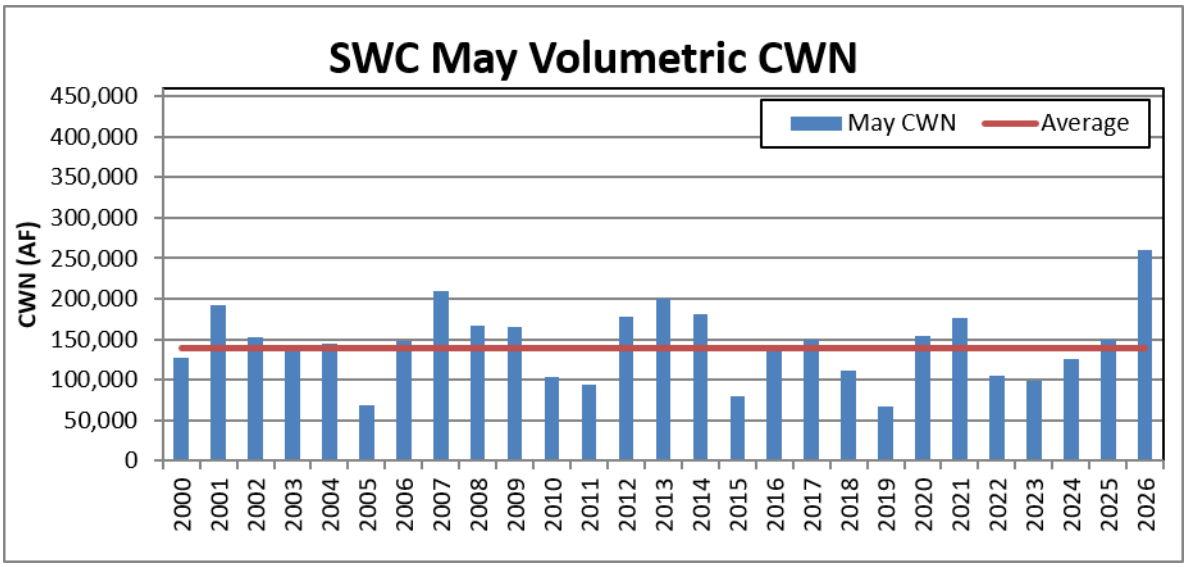
C. Reasonable In-Season Demand



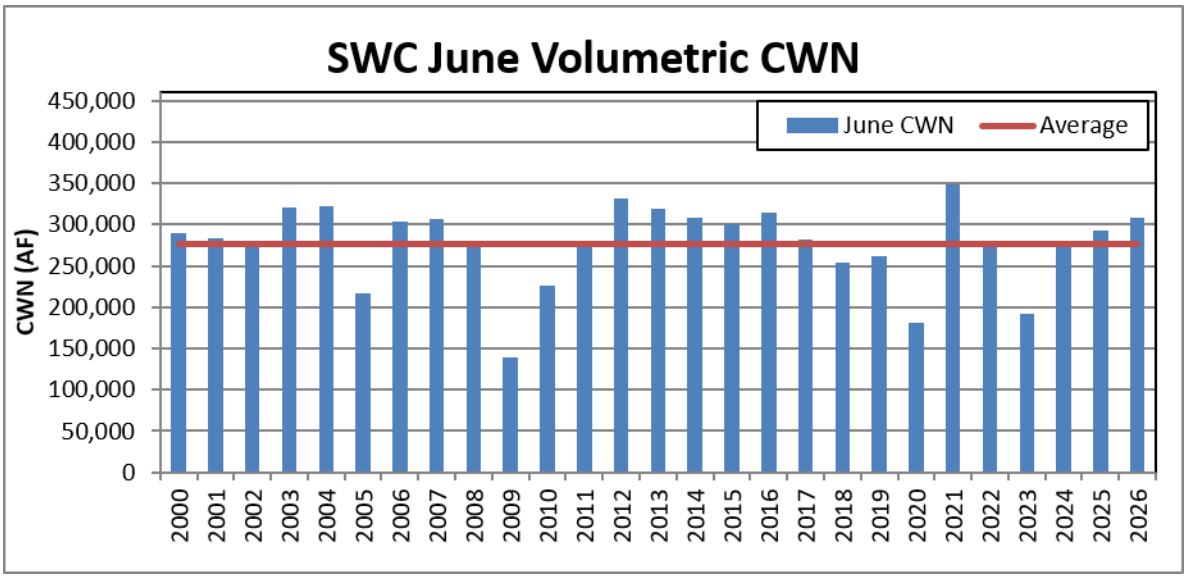
10. RISD "is the projected annual diversion volume for each SWC entity during the year of evaluation that is attributable to the projected beneficial use of growing crops within the service area of the entity." *Methodology Order*, at 13. In April, the demand from the 2018 baseline year ("BLY") defines the RISD. *Id.* at 17. During the irrigation season, the RISD for the completed portion of the irrigation season is recalculated by dividing the actual crop water need ("CWN") for each entity by the project efficiency for that entity. *Id.* at 17, 43. For the remainder of the irrigation season, the RISD is the demand defined by the July–October 2018 BLY. RISD is calculated on a monthly time step.



i. Crop Water Need



11. "CWN is the volume of irrigation water required for crop growth within a SWC entity boundary, such that crop growth is not limited by water availability." *Methodology Order*, at 15. " CWN is the difference between the fully realizable consumptive use associated with crop growth, or ET [evapotranspiration], and effective precipitation . . . ." *Id.*



12. CWN is an input variable for calculating RISD for the completed portion of the irrigation season. *Id.* at 17. Actual RISD for the completed portion of the irrigation season is combined with monthly predicted baseline demands for the remaining months of the irrigation season to calculate a season-total RISD volume. *Id.* at 17–18. In-season demand shortfall is then calculated as the difference between the adjusted FS and the RISD. *Id.* at 23.

13. As calculated from the beginning of the irrigation season (April 1), the SWC's volumetric CWN for the current water year through June 30, 2026, is 657,039 acre-feet. This volume is 137% of the 2000–2025 average CWN for April 1–June 30 and 142% of the CWN for the 2018 BLY. The following graphs summarize monthly volumetric CWN values:

ii. Extension of BLY

14. The RISD for the remaining portion of the irrigation season (July–October) is the July–October demand for the 2018 BLY. The numeric July–October demand values are shown in the table in Finding of Fact 15 below.

iii. Calculation of RISD

15. As calculated from the beginning of the irrigation season (April 1), the SWC's volumetric RISD for 2026 through June is 1,907,341 acre-feet. This volume is 142% of the 2000–2025 average demand from April 1–June 30 and 136% of the demand for the 2018 BLY. The recalculated RISD for each entity at this time is:

	April–June CWN (AF)	E_p (April–June)	April–June RISD (AF)	July–October Demand for 2018 BLY (AF)	Recalculated RISD (AF)
A&B	20,016	0.41-0.90	37,219	38,528	75,747[1]
AFRD2	71,135	0.20-0.38	252,302	274,485	526,787
BID	60,537	0.30-0.46	159,472	145,546	305,019
Milner	15,961	0.35-0.66	34,414	36,432	70,846
Minidoka	103,782	0.37-0.56	223,925	196,968	420,893
NSCC	161,932	0.21-0.40	583,376	594,099	1,177,475
TFCC	223,676	0.28-0.51	616,634	653,473	1,270,107

D. Forecast Supply

16. When calculated during the irrigation season, the FS is the sum of the year-to-date actual natural flow diversions, the forecasted natural flow supply for the remainder of the season, and the storage allocation for each member of the SWC. *Methodology Order*, at 43. For this order, the FS is the sum of the actual natural flow supply from April through June, the predicted natural flow supply from July through October, and the actual storage allocations. Actual natural flow diversions for the completed portion of the irrigation season are extracted from the Department's water rights accounting program. The natural flow diversions for the remainder of the irrigation season are estimated by regression analysis. *Id.* at 20–21, 43. Storage allocations are determined by Water District 01 after the Day of Allocation. *Id.* at 43.

i. Sum of Actual Natural Flow Diverted

17. Actual natural flow diverted for the period April through June for each SWC member are summarized in the table contained within the Summary of Forecast Supply section in Finding of Fact 25.

ii. Regression Models to Predict Natural Flow (July–October)

18. Natural flow diversions were predicted for the remainder of the irrigation season by regression analysis. The *Methodology Order* established the following predictor variables for the regression models: natural flow in the Snake River near Heise as reported by the BOR, snow water equivalent ("SWE") data from the Two Ocean Plateau SNOTEL site, Spring Creek discharge, and ground water levels near American Falls Reservoir. *Methodology Order*, at 20.

[1]The Department has modified the total A&B irrigated acreage count to 14,749 acres. Based on the decision in CV01-23-13238, the new acreage count removes A&B Irrigation District's enlargement acres.

Unique regression models with unique predictor variable groups are established in the *Methodology Order* for each SWC member. *Id.* at 20–21.

19. Either June 15 or July 1 SWE values for the Two Ocean Plateau SNOTEL site are used as input variables in each of the regression models developed in the *Methodology Order*. *Id.* Two Ocean Plateau SWE data was selected as a predictor variable in the *Methodology Order* based upon stepwise statistical analysis carried out in the development of each regression model. *Id.* The Two Ocean Plateau SWE data is an optimum predictor variable for several reasons, including: its elevation (the site is located above 9,000 ft and typically still has snow late in the runoff season (June 15 and July 1); its location (the site is in the headwaters of the Snake River above Jackson Reservoir); and its period of record, which is sufficiently long enough to support model development.

20. On July 1, 2026, the Two Ocean Plateau SNOTEL station reported 0.0 inches of SWE. When the snow water equivalent is zero on July 1, the predicted natural flow supplies for the period July 1–October 31 for A&B, AFRD2, and Milner are zero acre-feet. *Methodology Order*, at 20.

21. The input variables used to predict July–October natural flow volumes for BID, Minidoka, and NSCC in 2026 include: (1) 5.3 inches of SWE reported by the Two Ocean Plateau SNOTEL site on June 15, 2026; (2) 1,904,721 acre-feet of natural flow runoff at the Snake River near Heise (April–June) as reported by the BOR; and (3) 27.47 feet depth to water at well 05S 31E 27ABA1 as measured by the Department on March 23, 2026.

22. The variables used to predict the July–October natural flow volume for TFCC in 2026 include: (1) 5.3 inches of the SWE reported by the Two Ocean Plateau SNOTEL Site on June 15; (2) 1,904,721 acre-feet of natural flow runoff at the Snake River near Heise (April–June) as reported by the BOR; and (3) 66,070 acre-feet of discharge (January–May) as measured and reported by the United States Geologic Survey for its Spring Creek at Sheepskin Rd Nr Fort Hall ID Gage (Gage No. 13075983).

iii. Storage Allocations

23. Preliminary storage allocation values for each member of the SWC are summarized in the table in Finding of Fact 25 below. These values are established based on reported storage for each SWC entity in Water District 01's initial storage report published on July 9, 2026. These values include each entity's contribution to the Water District 01 Rental Pool flow augmentation program.

iv. Adjustments to Total Supply

24. Natural flow and storage water supplies were both adjusted, as shown in the table in Finding of Fact 25 below. The adjustments to natural flow depicted in the summary table were for water wheeled by BID and Milner for the Southwest Irrigation District. The adjustments to the stored water supply depicted in the summary table were for the Minidoka Credit.

v. Summary of Forecast Supply

25. The following table summarizes the calculated FS and its individual components for each of the SWC members.

	Natural Flow Diverted through 6/30 (AF)	Predicted Natural Flow 7/1 to 10/31 (AF)	Natural Flow Adjustment (AF)	Preliminary Storage Allocation (AF)	Minidoka Credit Adjustment (AF)	Forecast Supply (AF)
A&B	936	0	0	106,223	0	107,159
AFRD2	7,749	0	0	363,260	1,000	372,009
BID	59,430	0	(3,714)	197,196	5,130	258,042
Milner	4,976	0	(3,011)	71,870	0	73,835
Minidoka	74,482	0	0	273,676	8,370	356,528
NSCC	163,687	42,317	0	793,715	(7,750)	991,969
TFCC	393,054	367,366	0	227,002	(6,750)	980,672

E. Revised Shortfall Prediction

26. In-season demand shortfall ("IDS") is calculated as the difference between RISD and the FS.

27. Based on the established values above, and as summarized in the following table, the Director predicts that AFRD2, BID, Minidoka, NSCC, and TFCC will be materially injured by junior ground water pumping.

	Forecast Supply (AF)	RISD (AF)	Shortfall (AF)
A&B	107,159	75,747	0
AFRD2	372,009	526,787	154,800
BID	258,042	305,019	47,000
Milner	73,835	70,846	0
Minidoka	356,528	420,893	64,400
NSCC	991,969	1,177,475	185,500
TFCC	980,672	1,270,107	289,400
		Total	741,100

28. The current predicted shortfall to the SWC's RISD is 741,100 acre-feet.

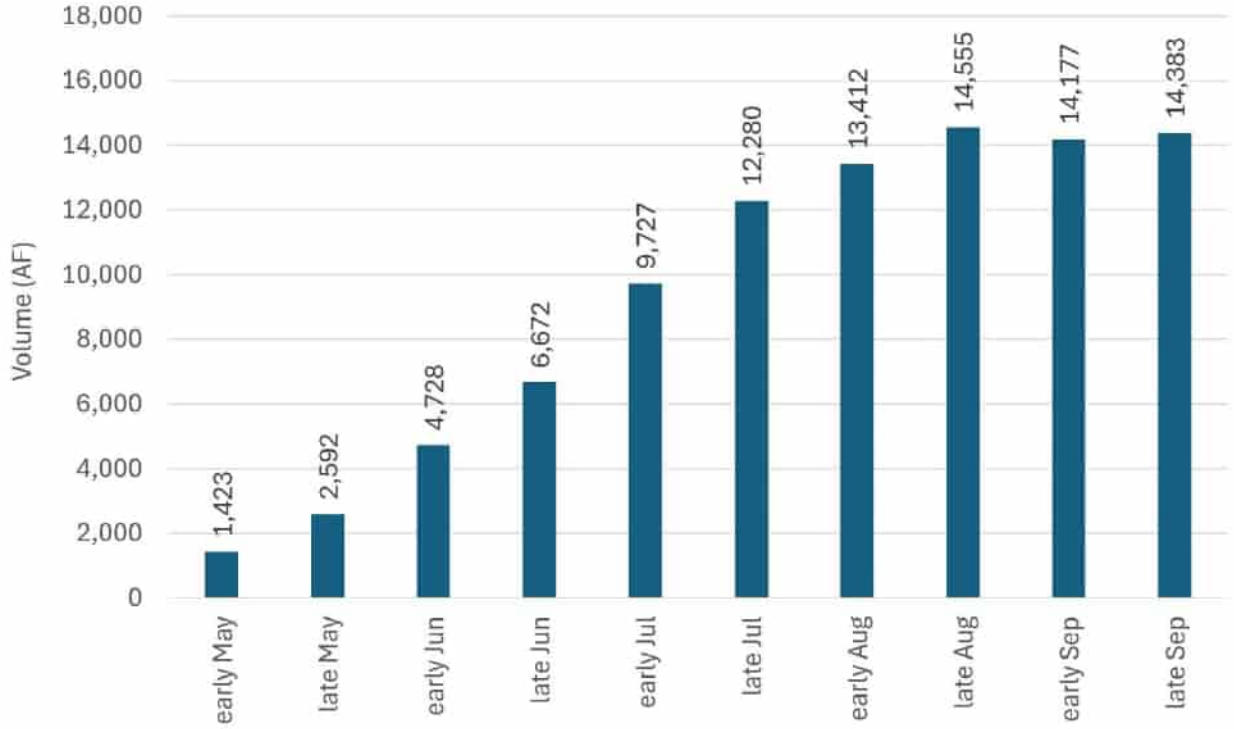
29. The Time of Need is used to determine when, during the water year, junior ground water users mitigating for their proportionate share using storage water must deliver that storage water to the SWC. No junior ground water users are mitigating for their proportionate share using storage water this year.

F. Step 6

30. Step 6 requires the following:

> Upon a determination of an additional mitigation obligation, junior ground water users will be required to establish, to the satisfaction of the Director, their ability to secure a volume of storage water or to conduct other approved activities pursuant to an approved mitigation plan that will deliver the additional mitigation obligation water to the injured members of the SWC at the Time of Need. If junior ground water users fail or refuse to submit this information within fourteen (14) days from issuance of a Step 6 order, the Director will issue an order curtailing junior ground water users. A transient ESPAM simulation will be run to determine the priority date to produce the necessary additional mitigation obligation volume by September 30 of the same year. Curtailment will be simulated within the area of common ground water supply, as described by CM Rule 50.01.

Methodology Order, at 44 (footnote omitted).



31. The total predicted July IDS for AFRD2, BID, Minidoka, NSCC, and TFCC is 741,100 acre-feet.

32. In April 2026, pursuant to the *Methodology Order*, the Department ran the Eastern Snake Plain Aquifer Model version 2.2 ("ESPAM2.2") to calculate the priority curtailment date, such that the curtailment of all water rights junior to the date within the ACGWS, would produce a volume of water equal to the April IDS in the Snake River between May 1 and September 30.[2] The ESPAM2.2 simulation predicted curtailment of ground water rights bearing priority dates junior to October 11, 1900, would produce a volume of water of 94,000 AF in the near Blackfoot to Minidoka reach between May 1 and September 30 of this irrigation season. The predicted benefit was less than the April IDS of 181,600 acre-feet. The Director concluded that curtailing ground water rights bearing priority dates junior to October 11, 1900, would offset as much of the April IDS as possible. *April Forecast Supply Order*, at 5.

33. In July 2026, the Department evaluated the effect of the simulated curtailment of ground water rights bearing priority dates junior to October 11, 1900, on near Blackfoot to Minidoka reach gains during July through September. The ESPAM2.2 simulation calculated that curtailment of ground water rights junior to October 11, 1900, would produce a volume of water

[2] Effective July 1, 2024, Senate Bill 1341 added a new section to Idaho Code, Idaho Code § 42-233c, which modified the description of the ESPA ACGWS. S.B. 1341, 67th Leg., 2d Reg. Sess. (Idaho 2024). In accordance with S.B. 1341, the Director subsequently expanded the ESPA ACGWS. In late 2025 and early 2026, the Director expanded the ESPA ACGWS to include the Raft River tributary basin and the remainder of the Little Lost River and Big Lost River tributary basins not already included in the ACGWS. On February 2, 2026, the Director issued an order declaring that ground water users included in the ESPA ACGWS in late 2025 and early 2026 would not be subject to administration before April 1, 2027. *Order Phasing in Administration of Ground Water Rights Recently Included in the ESPA ACGWS*, at 2. Accordingly, at this time, ground water users in the Raft River tributary basin and the remainder of the Little Lost River and Big Lost River tributary basins who were newly included into the ESPA ACGWS and hold consumptive water rights bearing priority dates junior to October 11, 1900, are not subject to administration.

of 78,500 AF in the near Blackfoot to Minidoka reach between July 1 and September 30 of this irrigation season. The following figure summarizes the results of the ESPAM2.2 simulation:

Modeled increase in ESPA discharge to near Blackfoot to Minidoka reach from curtailment of ground water junior to October 11, 1900

34. The predicted July through September benefits to the near Blackfoot to Minidoka reach from curtailment of ground water rights bearing priority dates junior to October 11, 1900, are less than the July IDS of 741,100 acre-feet. Continuing the curtailment of ground water rights junior to October 11, 1900, will offset as much of the July IDS as possible.

CONCLUSIONS OF LAW

1. Idaho Code § 42-602 authorizes the Director to supervise water distribution within water districts:

> The director of the department of water resources shall have direction and control of the distribution of water from all natural water sources within a water district to the canals, ditches, pumps and other facilities diverting therefrom. Distribution of water within water districts created pursuant to section 42-604, Idaho Code, shall be accomplished by watermasters as provided in this chapter and supervised by the director. The director of the department of water resources shall distribute water in water districts in accordance with the prior appropriation doctrine. The provisions of chapter 6, title 42, Idaho Code, shall apply only to distribution of water within a water district.

2. Idaho Code § 42-607 states the watermaster, under the direction of the Idaho Department of Water Resources, shall regulate diversions "during times of water scarcity, in order to supply the prior rights of others from such stream or water supply . . . ."

3. This year, no water is required to be allocated to the SWC pursuant to Step 5 related to a reasonable carryover shortfall because no junior water users secured water in 2025 to fulfill the carryover shortfall.

4. This year, because no junior ground water users are mitigating for their proportionate share using storage water, the Time of Need as described in Step 6 is not applicable.

5. Based on the Findings of Fact 6 through 27 above, it is reasonably certain AFRD2, BID, Minidoka, NSCC, and TFCC will be materially injured. The calculated shortfall to AFRD2, BID, Minidoka, NSCC, and TFCC is 741,100 acre-feet.

6. The May 14, 2026 *Curtailment Order* curtailed ground water users holding water rights bearing priority dates junior to October 11, 1900, which is the priority date equal to TFCC's Water Right No. 1-209, the most senior SWC natural flows water right predicted to be injured. Using the ESPAM2.2, the Department has determined that the continued curtailment of ground water rights bearing priority dates junior to October 11, 1900, would produce a volume of water of 78,500 AF in the near Blackfoot to Minidoka reach between July 1 and September 30 of this irrigation season. This would result in a volume of water less than the predicted July IDS of 741,100 acre-feet. Accordingly, continuing the curtailment of ground water rights junior to October 11, 1900, is necessary for curtailment to offset as much of the July IDS as possible.

7. Because the curtailment date remains October 11, 1900, the Director will not issue a new curtailment order under Step 6. The May 14, 2026 *Curtailment Order*, as subsequently modified by the June 17, 2026 *Order Amending Curtailment List to Include Unmitigated Ground Water Rights*, will remain in full force and effect.[3]

ORDER

Based upon and consistent with the foregoing, IT IS HEREBY ORDERED as follows:

The Director predicts an in-season IDS of 741,100 acre-feet. The May 14, 2026 *Curtailment Order*, as modified by the June 17, 2026 *Order Amending Curtailment List to*

[3] There are five approved mitigation plans responding to the SWC delivery call, each is stipulated to by the SWC: (1) No. CM-MP-2015-003 for the benefit of A&B; (2) No. CM-MP-2010-001 for the benefit of Southwest Irrigation District and Goose Creek Irrigation District (collectively, "SWID"); (3) No. CM-MP-2024-003 for the benefit of the Ground Water Districts; (4) No. CM-MP-2019-001 for the benefit of the Coalition of Cities; and (5) No. CM-MP-2007-001 for the benefit of the Water Mitigation Coalition. Due to the nature of the mitigation plans for A&B, SWID, the Ground Water Districts, the Coalition of Cities, and the Water Mitigation Coalition, these entities do not need to establish that they can mitigate for their proportionate share of the predicted IDS. On May 1, 2026, Hearing Officer Gerald Schroeder issued a *Preliminary Order Approving Falls Water's Stipulated Mitigation Plan* in Department Docket No. CM-MP-2026-002. Exceptions to the *Preliminary Order* are pending so the order has not become final yet pursuant to Idaho Code § 67-5245 and IDAPA 37.01.01.730.

Include Unmitigated Ground Water Rights, remains in full force and effect. All ground water users holding water rights listed in Attachment A to the May 14, 2026 *Curtailment Order* and listed in the June 17, 2026 *Order Amending Curtailment List to Include Unmitigated Ground Water Rights* bearing priority dates junior to October 11, 1900, shall continue to be curtailed from diversion and use of ground water pursuant to those water rights unless they are mitigating in accordance with an approved mitigation plan or are notified by the Department that the order of curtailment has been modified or rescinded as to their water rights.

Dated this 21st day of July 2026.

MATHEW WEAVER
Director

EXPLANATORY INFORMATION TO ACCOMPANY A FINAL ORDER

(To be used in connection with actions when a hearing was **not** held)

The accompanying document is a "**Final Order"** issued by the Idaho Department of Water Resources ("Department") pursuant to Idaho Code § 67-5246. The following statements describe the procedures and time limits for seeking reconsideration or other administrative relief as required by Idaho Code § 67-5248.

PETITION FOR RECONSIDERATION

(*See* Idaho Code § 67-5246(4))

Any party may file a petition for reconsideration of this final order within fourteen (14) days of the service date of this order as shown on the certificate of service. **Note: the petition must be received by the Department within this fourteen (14) day period.** The presiding officer will act on a petition for reconsideration within twenty-one (21) days of its receipt, or the petition will be considered denied by operation of law.

REQUEST FOR HEARING

(*See* Idaho Code § 42-1701A(3))

Unless the right to a hearing before the Director or the Water Resource Board is otherwise provided by statute, any person aggrieved by any final decision, determination, order, or action of the Director of the Department and who has not previously been afforded an opportunity for a hearing on the matter shall be entitled to a hearing before the Director to contest the action. The person shall file with the Director, within fifteen (15) days after receipt of written notice of the action issued by the Director, or receipt of actual notice, a written petition stating the grounds for contesting the action by the Director and requesting a hearing. **Note: The request must be received by the Department within this fifteen (15) day period.**

CERTIFICATE OF SERVICE

(*See* IDAPA 37.01.01.053, 37.01.01.202)

All documents filed with the Department in connection with a petition for reconsideration or a request for hearing of this final order shall be served on all other parties to the proceeding in accordance with Rules 53 and 202 of the Department's Rules of Procedure.

Attorney for Jerry D. Bingham and Valerie H. Bingham

BEFORE THE DEPARTMENT OF WATER RESOURCES

OF THE STATE OF IDAHO

IN THE MATTER OF DISTRIBUTION OF WATER TO VARIOUS WATER RIGHTS HELD BY OR FOR THE BENEFIT OF A&B IRRIGATION DISTRICT, AMERICAN FALLS RESERVOIR DISTRICT #2, BURLEY IRRIGATION DISTRICT, MILNER IRRIGATION DISTRICT, MINIDOKA IRRIGATION DISTRICT, NORTH SIDE CANAL COMPANY, AND TWIN FALLS CANAL COMPANY.	Docket No. CM-DC-2010-001 **JERRY D. BINGHAM'S AND VALERIE H. BINGHAM'S PETITION FOR RECONSIDERATION AND REQUEST FOR HEARING**

COME NOW Jerry D. Bingham and Valerie H. Bingham ("Binghams"), by and through counsel of record, and hereby petition the Idaho Department of Water Resources ("IDWR") for reconsideration pursuant to Idaho Code § 64-5246(4), and request a hearing in the above-referenced matter pursuant to Idaho Code § 42-1701A(3).

Binghams' water rights have been curtailed under the Director's Order Revising April 2026 Forecast Supply and Continuing May 16, 2026 Curtailment Order issued on July 21, 2026. As an aggrieved party, Binghams submit the following list of issues regarding the Director's order issued on July 21, 2026. These issues do not challenge the Director's authority to administer the Delivery

Call or mitigation requirements for In-Season Demand Shortfalls ("IDS"). Rather, they challenge whether the current methodology allocates mitigation responsibilities in a manner that is consistent, priority-based, and equitable. As currently implemented, the methodology imposes disproportionate obligations on certain groundwater users, including Binghams, while similarly situated water users, or more importantly users that are junior to Binghams, are treated differently or excluded from comparable responsibility. Binghams reserve the right to supplement this request as necessary.

1. Whether the Order Contains a Lack of Priority-Based Allocation Among Groundwater Users.

The Director's Order Revising April 2026 Forecast Supply and Continuing May 16, 2026 Curtailment Order focuses on junior groundwater users continuing to divert out of priority while not being administered on a time-priority basis for IDS responsibility. Specifically, the methodology appears to treat groundwater rights of different priorities as equivalent when assigning IDS responsibility. As a result, certain users, including Binghams, bear a disproportionate share of the mitigation burden while other junior-priority diversions continue to operate without a commensurate obligation.

Priority appears to be recognized for some administrative purposes but disregarded when allocating IDS responsibility. That raises a question of whether the methodology is consistent with the framework of the Idaho Constitution, Idaho statutes, and Conjunctive Management Rules (37.03.11 et seq.) requiring administration according to priority.

2. Whether Allocation of IDS Should be Assigned Only Among Groundwater Rights.

Under the Order Revising April 2026 Forecast Supply and Continuing May 16, 2026 Curtailment Order, the Director is apparently assigning IDS responsibility only among groundwater

users rather than among all water rights according to priority. By limiting responsibility to one category of users, the methodology creates a distinction between groundwater and surface-water rights that is not supported by the doctrine of prior appropriation. The July 21, 2026 Order focuses more on technical accounting than on the unequal treatment of similarly situated appropriators. By assigning IDS responsibility exclusively among groundwater users, the methodology departs from a priority-based administration framework and instead creates a categorical distinction between groundwater and surface-water rights not supported by governing law, including IDAPA 37.03.11, which provides for conjunctive management of surface and ground water resources; Idaho Code §§ 42-101 et. seq., which governs the use of any of the waters of the state to include both ground water and surface water; and Article XV of the Idaho Constitution.

3. Whether the Director's Order Uses Inconsistent Hydrologic Methodology.

The methodology of the Director's Order Revising April 2026 Forecast Supply and Continuing May 16, 2026 Curtailment Order applies different hydrologic assumptions to two mitigation mechanisms intended to address the same water-supply deficiency. This potentially results in disproportionate allocations of responsibility and an inequitable burden on affected water users.

Under the July 21, 2026 Order, storage obligations are allocated using long-term steady-state impacts, while conservation obligations are allocated under a different framework. The obvious question is whether there is a rational basis for valuing these mitigation actions under different hydrologic standards. The current methodology employed by the IDWR moves away from priority administration and instead relies on a series of administrative and methodological distinctions that produce unequal outcomes.

Binghams reserve the right to identify additional issues as necessary in this proceeding.

As previously stated above, Binghams petition IDWR for reconsideration of the Director's Order Revising April 2026 Forecast Supply and Continuing May 16, 2026 Curtailment Order pursuant to Idaho Code § 64-5246(4); and request a hearing pursuant to Idaho Code § 42-1701A(3). Binghams are aggrieved under Idaho Code § 42-1701A(3), as they have not been afforded an opportunity for a hearing on the Director's final order, and are entitled to an administrative hearing on the matter pursuant to Idaho law.

Respectfully submitted.

DATED this 3rd day of August, 2026.

COOPER & LARSEN, CHARTERED

By /s/ Reed W. Larsen
REED W. LARSEN
Attorney for Jerry D. Bingham and Valerie H. Bingham

STATE OF IDAHO

DEPARTMENT OF WATER RESOURCES

IN THE MATTER OF DISTRIBUTION OF WATER TO VARIOUS WATER RIGHTS HELD BY OR FOR THE BENEFIT OF A&B IRRIGATION DISTRICT, AMERICAN FALLS RESERVOIR DISTRICT #2, BURLEY IRRIGATION DISTRICT, MILNER IRRIGATION DISTRICT, MINIDOKA IRRIGATION DISTRICT, NORTH SIDE CANAL COMPANY, AND TWIN FALLS CANAL COMPANY	Docket No. CM-DC-2010-001 **IGWA'S RESPONSE TO JERRY D. BINGHAM'S AND VALERIE H. BINGHAM'S PETITION FOR RECONSIDERATION AND REQUEST FOR HEARING**

Idaho Ground Water Appropriators, Inc. ("IGWA"), through counsel and on behalf of its member ground water districts, submits this response in opposition to Jerry D. Bingham's and Valerie H. Bingham's Petition for Reconsideration and Request for Hearing ("Petition"), filed August 3, 2026, in this matter. As explained below, the Petition does not identify any error in the Order Revising April 2026 Forecast Supply and Continuing May 16, 2026 Curtailment Order issued July 21, 2026 ("July 2026 As-Applied Order") that warrants reconsideration.

The first issue for which the Binghams seek reconsideration—"whether the order contains a lack of priority-based allocation among groundwater users"—asks the Director to revisit the same proportionate-share theory A&B Irrigation District raised in response to the 2025 As-Applied Orders in this matter. *See A&B Proportionate Share Expert Report* at 4, Docket No. CM-DC-2010-001 (Nov. 7, 2025) ("ESPA methodology calculation of IDS is caused by decades of junior groundwater pumping, and the mitigation responsibility should consider priority. . . . IDWR should explain how the groundwater rights with a priority date senior to the time of over-appropriation are equally responsible for mitigating the IDS as groundwater rights junior to that time"). That case is now pending on appeal in Minidoka County District Court, Case No. CV34-26-462.

Reconsideration is not a vehicle for duplicative litigation of issues already presented in this contested case and now before the district court. *See Losser v. Bradstreet*, 145 Idaho 670, 674 (2008) ("This Court has emphasized the desirability of avoiding piecemeal litigation"). The Petition does not identify a distinct legal theory or materially different factual record that would justify

reopening that issue here. Therefore, the Department should decline to take up the issue again in the interest of orderly administration and judicial economy.

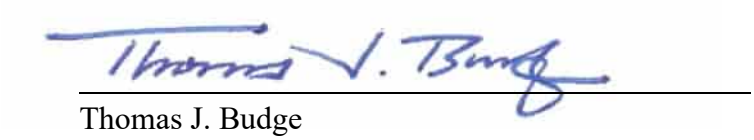
The Binghams' second issue—"whether allocation of IDS should be assigned only among groundwater rights"—misapprehends the scope of this proceeding. This matter involves the administration of groundwater rights under the Conjunctive Management Rules. It does not involve surface-to-surface water-right administration, which occurs within water districts under Idaho Code § 42-602. If the Binghams disagree with the way water districts are administering surface-water rights, they must challenge those actions in a separate proceeding, not through this conjunctive-management case. Because the Binghams' second issue falls outside the scope of this proceeding, reconsideration is improper.

The Binghams' third issue—"whether the Director's order uses inconsistent hydrologic methodology"—goes beyond the parameters of the July 2026 As-Applied Order. The Petition alleges that "storage obligations are allocated using long-term steady-state impacts, while conservation obligations are allocated under a different framework." Petition at 3. However, the July 2026 As-Applied Order does not allocate storage water or conservation obligations at all.

The Binghams appear to be conflating the July 2026 As-Applied Order with the mitigation plan approved in Docket No. CM-MP-2024-003 (the "2024 Plan"). Those are separate matters. The July 2026 As-Applied Order applies the Methodology Order to determine material injury under Conjunctive Management Rule 42. The 2024 Plan, by contrast, defines obligations of groundwater users participating in a mitigation plan approved under Conjunctive Management Rule 43. The July 2026 As-Applied Order and the 2024 Plan therefore address different questions under different rules. An alleged inconsistency between those separate administrative decisions is not an error in the July 2026 As-Applied Order and provides no basis for reconsideration.

To the extent the Petition challenges the Department's use of modeling at different steps in the Methodology Order, that issue also overlaps with A&B Irrigation District's challenge to the 2025 As-Applied Orders, which is on appeal. *See A&B Proportionate Share Expert Report* at 3 ("Whether the steady-state use of the ESPAM 2.2 in identifying A&B's proportionate share is consistent with the transient use of the model in identifying ground water rights subject to curtailment as outlined in the *Sixth Methodology Order*"). Accordingly, the Department should decline to take up the issue again in the interest of orderly administration and judicial economy.

For the foregoing reasons, the Department should deny the Petition.



DATED this 12th day of August, 2026.

BEFORE THE DEPARTMENT OF WATER RESOURCES

OF THE STATE OF IDAHO

IN THE MATTER OF DISTRIBUTION OF WATER TO VARIOUS WATER RIGHTS HELD BY OR FOR THE BENEFIT OF A&B IRRIGATION DISTRICT, AMERICAN FALLS RESERVOIR DISTRICT #2, BURLEY IRRIGATION DISTRICT, MILNER IRRIGATION DISTRICT, MINIDOKA IRRIGATION DISTRICT, NORTH SIDE CANAL COMPANY, AND TWIN FALLS CANAL COMPANY	Docket No. CM-DC-2010-001 **ORDER DENYING JERRY D. AND VALERIE H. BINGHAMS' PETITION FOR RECONSIDERATION AND REQUEST FOR HEARING**

BACKGROUND

On July 19, 2023, the Department issued its *Sixth Final Order Regarding Methodology for Determining Material Injury to Reasonable In-Season Demand and Reasonable Carryover* ("*Methodology Order*"). The *Methodology Order* established nine steps for determining material injury to members of the Surface Water Coalition ("SWC").

On July 21, 2026, the Director issued the *Order Revising April 2026 Forecast Supply and Continuing May 14, 2026 Curtailment Order (Methodology Steps 5-6)* ("*July As-Applied Order*"). The *July As-Applied Order* applied steps 5 and 6 of the *Methodology Order* and continued the effect of the *Final Order Curtailing Ground Water Rights Junior to October 11, 1900*, issued by the Director on May 14, 2026.

Step 5 of the *Methodology Order* addresses the final injury determination to reasonable carryover for members of the SWC. Step 5 states:

> If the storage allocations held by members of the SWC fill, there is no reasonable carryover shortfall. If the storage allocations held by members of the SWC do not fill, within fourteen (14) days following the publication of Water District 01's initial storage report . . . the volume of water secured by junior ground water users to fulfill the reasonable carryover shortfall shall be made available to injured members of the SWC.

Methodology Order, at 43.

Step 6 of the *Methodology Order* states:

> Approximately halfway through the irrigation season, but following the events described in Step 5, the Director will, for each member of the SWC: (1) recalculate RISD [Reasonable In-Season Demand]; (2) issue a revised FS [Forecast Supply]; and (3) estimate the Time of Need date.

Id. (footnote omitted).

Following the application of steps 5 and 6 of the *Methodology Order*, the Director issued the *July As-Applied Order*, predicting a July in-season demand shortfall of 741,100 acre-feet. *July As-Applied Order*, at 11. Due to the predicted shortfall, the Director ordered:

> The May 14, 2026 *Curtailment Order*, as modified by the June 17, 2026 *Order Amending Curtailment List to Include Unmitigated Ground Water Rights*, remains in full force and effect. All ground water users holding water rights listed in Attachment A to the May 14, 2026 *Curtailment Order* and listed in the June 17, 2026 *Order Amending Curtailment List to Include Unmitigated Ground Water Rights* bearing priority dates junior to October 11, 1900, shall continue to be curtailed from diversion and use of ground water pursuant to those water rights unless they are mitigating in accordance with an approved mitigation plan or are notified by the Department that the order of curtailment has been modified or rescinded as to their water rights.

Id. at 11–12.

On August 3, 2026, Jerry and Valerie Bingham ("Binghams") filed with the Department, *Jerry D. Bingham's and Valerie H. Bingham's Petition for Reconsideration and Request for Hearing* ("*Petition and Request*"), challenging the *July As-Applied Order*. *Petition and Request*, at 1.

On August 12, 2026, Idaho Ground Water Appropriators, Inc. ("IGWA") filed *IGWA's Response to Jerry D. Bingham's and Valerie H. Bingham's Petition for Reconsideration and Request for Hearing* ("*Response*"). The *Response* argues the Binghams fail to identify any error in the *July As-Applied Order* that warrants reconsideration. *Response*, at 1.

ANALYSIS

The Binghams' filing is styled as both a petition for reconsideration and a request for hearing. While the analysis of the petition for reconsideration and the request for hearing is largely similar, the Director will consider the merits of each request separately.

1. The Binghams identify no basis to reconsider the *July As-Applied Order*.

Idaho Code § 67-5246(4) governs petitions for reconsideration of final orders. It states:

> Unless otherwise provided by statute or rule, any party may file a motion for reconsideration of any final order issued by the agency head within fourteen (14) days of the service date of that order. The agency head shall issue a written order disposing of the petition. The petition is deemed denied if the agency head does not dispose of it within twenty-one (21) days after the filing of the petition.

The *Petition and Request* filed by the Binghams states that they seek reconsideration of the *July As-Applied Order*. The *July As-Applied Order* applied Steps 5 and 6 of the *Methodology Order*. *July As-Applied Order*, at 1–2, 11. Step 5 addresses the final determination of injury to

reasonable carryover. *July As-Applied Order*, at 1; *see also Methodology Order*, at 43. Step 6 requires the Director to recalculate the reasonable in-season demand and revise the forecast supply. *July As-Applied Order*, at 2; *see also Methodology Order*, at 43. The *July As-Applied Order* made the determinations required by those steps. *July As-Applied Order*, at 11.

The fundamental problem with the Binghams' petition for reconsideration is that the Binghams do not identify a finding of fact, conclusion of law, calculation, or directive in the *July As-Applied Order* that they contend is erroneous and should be reconsidered. They do not challenge the Director's Step 5 determination, the recalculated reasonable in-season demand, the revised forecast supply, the resulting in-season demand shortfall, or the factual information and calculations underlying those determinations. Instead, the three issues identified in the *Petition and Request* concern the structure of the underlying methodology and the allocation of mitigation responsibilities—matters not determined by the *July As-Applied Order*. *See Petition and Request*, at 2–3.

The Binghams' own description of their challenge confirms this conclusion. They state that their "issues do not challenge the Director's authority to administer the Delivery Call or mitigation requirements for In-Season Demand Shortfalls," but instead "challenge whether the current methodology allocates mitigation responsibilities in a manner that is consistent, priority-based, and equitable." *Petition and Request*, at 1–2. Thus, although the Binghams say they seek reconsideration of the *July As-Applied Order*, the substance of their challenge is directed to the *Methodology Order* and framework for allocating mitigation responsibilities under the SWC Delivery Call.

A petition for reconsideration of the *July As-Applied Order* must identify a basis for the Director to reconsider a determination made in the *July As-Applied Order*. The Binghams identify none. Their three stated issues instead challenge the *Methodology Order* and the framework for allocating mitigation responsibilities under the SWC Delivery Call—matters that were not established or decided in the *July As-Applied Order*. The methodology underlying the SWC Delivery Call has been the subject of extensive litigation. The Idaho Supreme Court has affirmed that the Director may employ a baseline methodology as a starting point for administration of the interconnected surface and ground water rights at issue in the SWC Delivery Call. *In Matter of Distribution of Water to Various Water Rts. Held By or For Ben. of A & B Irrigation Dist.*, 155 Idaho 640, 650, 315 P.3d 828, 838 (2013). In 2023, following an administrative hearing concerning the revisions to the methodology, the Director issued the current *Methodology Order* as a final order of the Department. Certain aspects of the *Methodology Order* were challenged on judicial review, and Judge Wildman affirmed the Department. *City of Idaho Falls v. Idaho Dep't of Water Res.*, No. CV01-23-13238 (Ada Cnty. Dist. Ct. Idaho 2024); *Memorandum Decision and Order*, at 27, *Idaho Ground Water Appropriators Inc. v. Idaho Dep't of Water Res.*, No. CV01-23-13173 (Ada Cnty. Dist. Ct. Idaho May 31, 2024). [1] The Binghams cannot use a petition for reconsideration of the *July As-Applied Order* to collaterally challenge determinations made in the *Methodology Order*. Because the

[1] In No. CV01-23-13173, one challenge remains pending because the matter was stayed during proceedings on reconsideration.

Binghams identify no error in the findings, calculations, conclusions, or directives contained in the *July As-Applied Order*, the *Petition for Reconsideration* should be denied.

2. The Binghams' request for hearing does not state grounds for contesting the *July As-Applied Order*.

Idaho Code § 42-1701A(3) governs petitions requesting a hearing before the Department. It states, in pertinent part:

> [A]ny person aggrieved by any action of the director, including any decision, determination, order or other action, including action upon any application for a permit, license, certificate, approval, registration, or similar form of permission required by law to be issued by the director, who is aggrieved by the action of the director, and who has not previously been afforded an opportunity for a hearing on the matter shall be entitled to a hearing before the director to contest the action. The person shall file with the director, within fifteen (15) days after receipt of written notice of the action issued by the director, or receipt of actual notice, a written petition stating the grounds for contesting the action by the director and requesting a hearing.

Idaho Code § 42-1701A(3) therefore entitles a person aggrieved by an action of the Director, who has not previously been afforded an opportunity for a hearing on the matter, a hearing to contest the action. The petition must state the grounds for contesting the Director's action.

The Binghams request a hearing on the *July As-Applied Order*. As discussed above, however, the *Petition and Request* does not identify a determination made in the *July As-Applied Order* that the Binghams seek to contest. They do not challenge the Director's Step 5 determination, recalculation of reasonable in-season demand, revised forecast supply, resulting in-season demand shortfall, or the factual information and calculations underlying those determinations. Instead, the Binghams expressly state that their issues "challenge whether the current methodology allocates mitigation responsibilities in a manner that is consistent, priority-based, and equitable." *Petition and Request*, at 2. The grounds stated in the *Petition and Request* thus concern the validity and structure of the *Methodology Order* and the framework for allocating mitigation responsibilities under the SWC Delivery Call, not the determinations made in the *July As-Applied Order*. The distinction is significant under Idaho Code § 42-1701A(3). To the extent the Binghams seek a hearing to contest the determinations made in the *July As-Applied Order*, their petition does not state grounds for contesting those determinations. To the extent they instead seek a hearing to challenge the *Methodology Order*, Idaho Code § 42-1701A(3) does not permit the Binghams to obtain a hearing on the *Methodology Order* merely by directing their request at a later as-applied order. The *Methodology Order* was issued in 2023, following an administrative hearing pursuant to Idaho Code § 42-1701A(3), and has already been subject to judicial review. Because the Binghams state no grounds for contesting the determinations made in the *July As-Applied Order*, the request for hearing should be denied.

ORDER

IT IS HEREBY ORDERED that *Jerry D. Bingham's and Valerie H. Bingham's Petition for Reconsideration and Request for Hearing* is DENIED.

Dated this 24th day of August 2026.

EXPLANATORY INFORMATION TO ACCOMPANY AN ORDER DENYING PETITION FOR RECONSIDERATION OF A FINAL ORDER

(To be used in connection with Final Orders, reconsideration of which is now denied, issued by the Director or the Board)

The accompanying document is an **Order Denying Petition for Reconsideration** of the "**Final Order**" issued previously in this proceeding by the agency head of the Idaho Department of Water Resources ("Department") or the Idaho Water Resource Board ("Board") pursuant to Idaho Code § 67-5246.

The following statements describe the procedures and time limits for seeking appeal of the final order previously issued in this proceeding:

APPEAL TO DISTRICT COURT

(*See* Idaho Code §§ 67-5270 through 67-5279)

Within twenty-eight (28) days after the service date of the presiding officer's denial of a petition for reconsideration, any party may file a petition for judicial review of the final order with a district court. Filing an appeal to a district court does not in itself stay the effectiveness or enforcement of the final order appealed.

FILING AND SERVICE

(*See* I.R.C.P. 84)

Any petition for judicial review filed in connection with an appeal of the final order shall be served on the agency and all parties to the administrative proceeding in accordance with Idaho Rule of Civil Procedure 84.

Attorneys for A&B Irrigation District, Burley Irrigation District, Milner Irrigation District, North Side Canal Company, & Twin Falls Canal Company

BEFORE THE DEPARTMENT OF WATER RESOURCES

OF THE STATE OF IDAHO

IN THE MATTER OF DISTRIBUTION OF WATER TO VARIOUS WATER RIGHTS HELD BY OR FOR THE BENEFIT OF A&B IRRIGATION DISTRICT, AMERICAN FALLS RESERVOIR DISTRICT #2, BURLEY IRRIGATION DISTRICT, MILNER IRRIGATION DISTRICT, MINIDOKA IRRIGATION DISTRICT, NORTH SIDE CANAL COMPANY, AND TWIN FALLS CANAL COMPANY	Docket No. CM-DC-2010-001 **DIRECT TESTIMONY OF JAY BARLOGI**

Q. CAN YOU PLEASE STATE YOUR FULL NAME AND ADDRESS?

A. My name is Jay Barlogi and I live at 212 6th Street in Filer, Idaho.

Q. CAN YOU DESCRIBE YOUR BACKGROUND?

A. I grew up near Curry and I graduated from Filer High School. I started working for Twin Falls Canal Company in 1993. I worked as a Ditch Rider for three years, then as the East End

Watermaster for about 14 years, then as the Field Supervisor before being appointed as the General Manager in June 2021.

Q. DID YOU SUBMIT PRE-FILED TESTIMONY IN THIS PROCEEDING BACK IN 2005?

A. Yes.

Q. DID THAT TESTIMONY FAIRLY DESCRIBE THE VARIOUS WATER DELIVERY RELATED ROLES IN THE COMPANY?

A. Yes. Those duties are pretty much the same today, except that the Watermasters probably interact more with the Ditch Riders for purposes of quality assurance and periodically reviewing return flow spills off the project. TFCC delivers water to shareholders at over 4,000 headgates spread out on a landscape of approximately 315 square miles. The company employs 3 Water Masters, and 3 Dam Tenders to tend to the duties at Milner Dam, Murtaugh Lake Dam, and the Forks, where the Mainline Canal bifurcates into the High Line Canal and the Low Line Canal. These Water Masters and Dam Tenders regulate the Flow of water in the over 100 miles of Main Canals. A team of 24 Ditch Riders then divert water out of the main canal and into over 1,000 miles of smaller delivery canals and divert and measure water to the shareholder via over 4,000 headgates. Water Masters, Dam Tenders, and Ditch Riders are highly trained in water management and water measurement. While many canal companies simply claim to measure all of the water that is conveyed and delivered within their systems, The Twin Falls Canal Company meticulously measures the water within the system and at the headgates on a daily basis throughout the irrigation season.

Q. WHAT ARE YOUR GENERAL RESPONSIBILITES AS GENERAL MANAGER?

A. I oversee the operation and maintenance of the Twin Falls Canal Company and the canal system described above that delivers water represented by 202,690.93 water shares to shareholders in our project. I am responsible for the supervision of 65 full time employees, company property management, and company budget and finances.

Q: HAVE THE COMPANY'S INTERNAL WATER DELIVERY AND MAINTENANCE OPERATIONS CHANGED SUBSTANTIALLY SINCE 2010?

A. No, from an overall standpoint our operations to maintain the canal system and deliver water are in line with our past practices over the past ten years.

Q. WHAT CHANGES OR EXTERNAL FACTORS HAVE YOU NOTICED THAT HAVE IMPACTED YOUR WATER DELIVERY OPERATIONS?

A. Several things have changed since 2010 that have impacted our operations. The Dairy industry in the area to a large extent has re-defined the crop mix in the area. Crop mix dictates water demand, and water demand dictates diversions and delivery schedules. Conversion from gravity irrigated acres to sprinkler irrigated acres continues on the project, and has had an effect on the company's ability to re-use waste water within the system. Development in the area has become a challenge as we work hard to protect the canal system and our ability to maintain the system as land use changes from agricultural uses to residential, commercial and industrial uses.

Q. CAN YOU GENERALLY DESCRIBE WATER DELIVERY OPERATIONS?

A. I have listed a brief summary of our water operations over the course of an irrigation season by month below:

April

April 1st typically marks the start of the irrigation season each year. We usually tell shareholders water will be available within a week of April 15th depending upon the year. This is the time when canal operators begin preparing for the irrigation season ahead. First, we prepare the canal system for water, burn weeds out of the canals, shape the canals and in general make sure that the waterways within the system are in good shape to begin the irrigation season. Second, we have to "charge" the system. Snowpack, water supply, and weather conditions are all accounted for when the date is determined when canal managers must make water available for delivery to the water users.

The TFCC canal system consists of over 100 miles of main canals, and over 1,000 miles of smaller delivery canals with multiple canal deliveries on each of the Main Canal and smaller canals. It requires 7 to 10 days to "charge" the system depending on the weather conditions. Watermasters and Ditch Riders work together to bring the water into the system and prepare for that eventual "delivery date". Once the system is fully charged, Ditch Riders begin taking water orders. Shareholders will contact their appropriate Ditch Rider and order their water on. At this point Ditch Riders will communicate every day with their Water Masters to relay the amount of water being diverted to shareholders so that the Water Masters can manage the flows in the main canal. Just like balancing your checkbook, if we divert more water out of the canal system to water users than the canal system contains, water users at the end of the system will dry up. Decisions are made and adjustments are made daily to ensure the balance of water within the canal system will sustain the needs of the water users. On the converse side of the issue, unlike balancing your checkbook, if more water is brought into the system than water orders demand,

flooding can occur at the tail end of the system, as the canals at the tail end of the system are significantly smaller than the canals at the head end of the system.

Water users in the early part of the season surprisingly order much of their water on in April. Farming practices are different in an open channel system in that each headgate may service multiple fields and not just a single large potato field or corn field. Water users may need to build some moisture into the soil profile to begin working the land and prepare for the ultimate planting of the crops. Depending upon climatic conditions, water users in April can begin irrigating pasture lands, grain crops, sugar beets and alfalfa crops too. Water users also often have an extensive ditch system of their own and may order water in early just to prepare and "charge" their own individual systems. Finally, Water Users often have pasture that they would like to put water on early in the season to free up the duty of their water later in the season when the farm crop needs the water. Keep in mind, that the dairy industry remains in need of feed, and after a long winter their feed supply has dwindled and they are anxious for that first cutting of hay as soon as possible, leading producers to get water to the alfalfa fields quickly.

Mother Nature can be fickle, and often this time of year Water Managers plan to meet the needs of the Water Users, Water Users plan to meet the needs of the crops, and Mother Nature steps in and changes everyone's plans. It is not unusual for a rainstorm or even a snowstorm to move through the area and completely remove the need for any water use. Inevitably those wet days will be followed by 2 or 3 warm dry days when the wind blows and dries everything out to the point of everybody being behind again. Rinse and repeat 2 or 3 times each spring. The size of the Twin Falls Canal system is such that it takes 3 days to get water from the Snake River to the end of the canal system, this makes reacting to these kinds of events very difficult given the clarity of our crystal ball.

May:

A typical May is anything but typical as weather conditions from year to year are never the same. Weather in May often causes us to experience snow, rain, wind, and a few days later, near 90-degree temperatures. Water users in May are generally making sure that pasture lands, grain crops, sugar beets and alfalfa crops are being watered in an attempt to ensure that water is available to pre-water for dried bean and corn crops to be planted late May and early June as weather conditions often create the need for. This variability in weather creates a challenge for water managers as they attempt to react to ever changing weather conditions and watch weather forecasts in an effort to plan and prepare for water diversions in the coming days. It is not uncommon for water managers to bring water into the system to meet the expected future demands, and experience rainy and wet weather for the next two or three days. The opposite also occurs when water managers react to wet and cold temperatures resulting in little demand to be followed by nearly 90-degree temperatures and twenty-mile per hour winds.

June/July/August:

June, July and August represent the "meat" of the irrigation season. During this period of time diversions are commonly at or near the highest diversion rates of the season as we experience peak demands. All of the crops on the system will require water and Water Users will carefully schedule their water supply to meet the needs of their crops. A Water User that gets behind in his water schedule this time of year will likely not find an opportunity to catch back up without stressing crops somewhere on his farm. Since crop water needs can exceed deliveries during this time it highlights the importance of early season watering to build soil moisture profiles. Company water managers *(Ditch Riders and Water Masters)* will carefully measure and lock all water deliveries and be required to have acute focus on canal system water elevations in an effort

to provide a high level of continuous water delivery to our Water Users while operating the canal system in a prudent manner to ensure no loss of delivery as a result of a canal break. Company Maintenance crews are very busy this time of year cleaning canals, managing weed growth, management of aquatic weed growth, and managing sediment within the system in the many sedimentation ponds that exist within the system.

September:

September historically has marked the beginning of the end of the irrigation season. Diversions in the past would be on a steady decline and crop demands dropped and diversions reduced as many crops have been harvested or are reaching maturity and are soon to be harvested. In recent years the month of September has changed somewhat. The smell of fall is certainly still in the air when September arrives and many of the same reduced demand and diversions the we have experienced in the past remain true, the reduction in diversion and demand are not at the same level that they were previously. Producers who were historically content with three cuttings of alfalfa per year now find themselves attempting to meet the demands of the dairy industry and aspire to obtain four and even five cuttings per year. This increase in alfalfa production has resulted in increased late season demand for water. The corn acreage on the project have increased significantly in recent years as well in response to the needs of the dairy industry. Historically there were several thousands of acres of sweet corn produced on the project and the Green Giant Company had a processing plant in Buhl. Several years ago the Green Giant plant closed its doors and the sweet corn crop which had a shorter growing season has now been replaced with the much more water consumptive field corn varieties. This too has resulted in increased late season demand in September. September can also feel the effects of an

unusually cold and wet spring that delays the planting of many of the more water intensive crops thereby extending the irrigation needs of the crop later into the year.

October:

Demands for water delivery in October have changed to an extent over the years. Certainly, demand for water begins to decline as crops are harvested and the end of the season is near, but canal operators cannot simply shut the water off to the shareholders if they choose to continue to receive water. The dairy industry has created a portion of the change as some producers have started double cropping and when their crop is harvested they will quickly plant triticale to either green chop for the dairies or graze. Most alfalfa hay producers in the area have historically been content with 3 cuttings per year but the dairy industry and the never-ending need for feed has resulted in many producers striving to get 5 cuttings per year and driving the late season demand. Years with particularly wet springs can also create a delay in the corn planting, cooler winters can create a delay in the corn harvest, both resulting in late season demands being higher in recent years than they have been in the past. Cover crops and soil health concerns have created a late season demand as producers will plant a cover crop in the fall to improve soil health, increase agricultural productivity, and build climate resilience.

Q. HAVE YOU NOTICED ANY CROPPING PATTERN CHANGES IN THE LAST 10-15 YEARS?

A. With the dairy industry looming so large in the county, it's no surprise that the industry has a major effect on the local and state economy, and supports 10's of thousands of jobs in the area. For cows to produce milk they require feed, and feed requires water. Much of the farm economy in Twin Falls County is now supported by the dairies. A significant increase in forage crops, Alfalfa Hay, Corn, and Triticale are now in considered staple crops within the TFCC tract.

The historical crop rotation that included Alfalfa, dry beans, corn, wheat and barley, sugar beets and potatoes, has changed dramatically as a result of the dairy industry. Current crop rotation includes significantly more acres of the big water consumers, alfalfa hay, and corn. In an effort to continue to provide a consistent reliable delivery of water to the agricultural producers in the county, The Twin Falls Canal Company has no doubt had to focus on efficiencies in an effort to provide water to this new cropping landscape while operating within our water right.

Q. WHAT HAVE YOU NOTICED ABOUT DOUBLE CROPPING ON THE PROJECT OR OTHER LATE SEASON WATER USE?

A. In addition to the increase in more water intensive crops being introduced into the local crop mix, there is also an increase in double cropping as producers continue to attempt to meet the needs of the dairy industry. Each year more and more acres of grain or beans are harvested, and producers prepare the field for a late crop of triticale. If shareholders have his late season demand we will continue to make those deliveries as requested within our water right.

Over and above the double cropping, there has been in recent years more emphasis on soil health as producers will plant a cover crop in the fall to improve soil health, increase agricultural productivity, and build climate resilience.

Q: CAN YOU GENERALLY DESCRIBE THE COMPANY'S MAINTENANCE ACTIVITIES?

A. To a great extent, all canal maintenance activities are performed to target efficiencies. As stated, before in this document, canal system capacity dictates maintenance activities to provide consistent reliable water delivery to all shareholders while protecting the integrity of the canal

system. It is impossible to protect the integrity of the canal system and operate the system over and above the designed capacity of the system at the same time.

Canal Cleaning:

Twin Falls Canal Company has always boasted to having the largest construction company in the area. With 9 excavators, two backhoes, 3 bulldozers, 2 road graders, a fleet of 10, 15-yard capacity dump trucks, 3 loaders, 12 tractors and a large assortment of trucks and trailers, we are the only construction crew in the area that works all year long. Winter, Spring, Summer, and Fall, Twin Falls Canal Company crews are on the job site. Many contractors in the area have *(tongue in cheek*) thanked us over the years for providing a training ground for equipment operators in the area.

Some of the best excavator operators in the area are in a constant effort to clean the canals on the project. With over 100 miles of main canal and over 1,000 miles of smaller canals it is truly a job that is never done. Sediments fall out of the irrigation water and deposit in the canal bottoms to the point that water management staff cannot push the necessary flow of water through the canals. When canals get in this condition, evaporation increases and more and more water soaks into the canal banks as water rises to overcome the partial blockage in the canals. Without these crews and machinery, efficiency would suffer tremendously as canal operators would be forced to bring in more water in an attempt to push through the partially blocked section of canal. A big part of operating a canal system efficiently is regular maintenance of the system. The Twin Falls Canal Company maintains millions of dollars' worth of equipment and expends nearly $1,500,000 per year in payroll just for the maintenance crews that take care of the Twin Falls Canal Company canal system.

Aquatic Plant Growth Management:

Aquatic Plant Management is another part of canal system maintenance that is not only a never-ending job, but an absolute essential activity required of canal maintenance crews in an effort to make the canal system as efficient as possible. As aquatic plants begin to grow in the canal system each year, they, much like the sediment can completely ruin a canals ability to flow freely. When this ability to flow freely is compromised, water elevations rise, evaporation loss increases, water soaks into the perimeter of the canal at a much higher rate, and canal operators are forced to either push harder with more water to get the water to flow through the canals or remove the aquatic plant growth. Removal of the aquatic plants is no easy task. Twin Falls Canal Company Crews use a multitude of methods to remove the plants including, cleaning the canals with excavators, dragging heavy chains through the canals in an effort to make the plant break loose, or chemical removal of the plants. The Twin Falls Canal Company spends over $500,000.00 per year for chemicals to remove the moss and aquatic plants that grow in the canals and threaten canal operation efficiency.

The picture above shows how moss can obstruct flow in a lateral.

The picture above is an example of our chemical treatment application to manage aquatic weed growth.

Weed Spraying and Mowing Program:

Weeds growing along the edge of the canals are a definite challenge to open system canal operating efficiencies. As weeds and grasses grow on the sides of the canals there is no doubt where they are getting the water that sustains their growth, but that is only part of the issue. As these weeds and grasses approach maturity in the heat of the season the begin to fall over into the flow of the canals and just like the aquatic plant growth, they attempt to occlude the path of the water flow. Water managers are forced to either push harder with more water or remove the obstacle. The Twin Falls Canal Company crews operate 10 mowing tractors throughout the irrigation season in an attempt to combat this weed growth and allow the water in the canals to flow freely. The Twin Falls Canal Company also employe 2 employees who have the responsibility to operate our two spray trucks throughout the season and apply weed spray in our continued effort to complete yet another job that is never done. Cost of the weed spraying and mowing crews annually is nearly $350,000.00.

The above shows a typical mowing operation to cut weeds and grass on the side of a main canal.

This picture shows removal of grass and weeds that have covered a lateral.

Canal Piping:

Continued use and maintenance of open channels in residential, commercial, or industrial areas can be difficult. Piping waterways can have a positive impact on these operations and can help efficiencies by preventing water loss. We have worked closely with the cities that exist within our project boundaries and the county planners, to require developers to pipe waterways when land use changes from agricultural uses to residential, commercial, or industrial uses. Many miles of open waterways have been piped over the course of the last 20 years and local officials and the Twin Falls Canal Company will continue to require that piping.

Russian Olive Removal

If you have a chance to look at aerial imagery of the Twin Falls Canal Company tract in the 1960's you will definitely notice an absolute absence of the Russian Olive trees that have now infested every corner of the tract. These trees although drought tolerant prefer to grow at water's edge along any waterway they take root in. These trees can consume 10 to 20 gallons of water per week per tree. Not only do they drink an enormous amount of water but they too like the weeds and grasses along the canals have the tendency to grow out in the waterway and fall over in the waterway. Management of the Twin Falls Canal Company was at the leading edge of a movement a few years ago to try to get the Russian Olive tree listed as a noxious weed in Idaho and establish a path forward in eradicating these trees from our state. That Movement was ultimately unsuccessful and The Twin Falls Canal Company Crews will have to continue the methods of management that we have embraced as a part of our responsibility to ensure the most efficient use of the water. Twin Falls Canal Company Crews have for years identified specific problem areas, and worked with property owners in those areas to remove large growths of Russian Olive from the banks of the canals.

Q: WHAT ARE THE IMPROVEMENTS THE COMPANY HAS MADE FROM A WATER DELIVERY STANDPOINT SINCE YOU STARTED WORKING?

A: In addition to all the work listed above, we have undertaken the following to improve water deliveries and ensure efficient canal operations.

Automation:

In the early 90's the Twin Falls Canal Company recognized the affect that potential crop mix changes and conversion to sprinkler would have on the company's ability to continue to provide a consistent and reliable water delivery to all of its shareholders, and embarked on a mission to install automation within the canal system to improve canal efficiencies and address these challenges. Currently the canal system has nearly 60 automated sites that measure, regulate, and limit water flows within the system to help us make sure that the water gets where it needs to go while minimizing waste and providing a timely and high level of service to our water users. The bulk of the Automation equipment has been Sutron brand equipment, but we have also used technology from Langman Automated Gate Systems from Canada, Rubicon Water Slip-meters and Piko-meters from the Rubicon Water Company in Australia, and Obermeyer Hydro in Fort Collins Colorado.

These automated sites come at a high cost and the Twin Falls Canal Company has partnered with shareholders, and secured grant funding through the Bureau of Reclamation WaterSmart program as well as the Idaho Water Resource Board funding. At an overall cost of well nearly $5,000,000.00, and annual costs of over $100,000.00, the Twin Falls Canal Company commitment to canal efficiency is obvious, unparalleled, and ongoing.

These pictures show examples of automated gates on the canal system.

Concrete Structures:

The Twin Falls Canal Company Tract is home to over 10,000 concrete structures. The structures are all designed to manage, regulate and measure the flow of water within the canal system. Although concrete is a durable and long-lasting product, it too has a life span. If Twin Falls Canal Company crews replace 100 concrete structures per year, the concrete inventory can be turned over once every 100 years. A very important part of the maintenance crew's responsibility is keeping concrete structure inventory up to date and replacing and improving concrete measurement facilities, as these structures are key to efficient operation of the canal system.

Canal Lining:

Canal Lining projects that have taken place for decades (likely over a century) on the Twin Falls Canal Company canal system. Recently we have done 2 large scale lining projects with HDPE liners and have another project scheduled for next year (2023-2024), but that doesn't suggest that lining projects are new to the Twin Falls Canal Tract. Liner projects have always been a part of our annual maintenance activities throughout the entire existence of the tract, and crews have for years removed gravelly materials from canal bottoms and hauled in huge amounts of good clay material, bentonite, cinders and polyacrylamide to line canals. These and many other activities aimed at constant improvement of our system efficiencies have always been and continue to be considered a huge part our responsibility in the operation of the canal system. The first picture below shows an example of a clay material lining project on the Low Line Canal. The next picture shows installation of the HDPE liner we installed on the High Line Canal in 2019.

Padlocks:

Many don't realize that the 4,000 + headgates that the Twin Falls Canal Company uses to measure and deliver water to the shareholders are really a 2 structure gate system. To lock one of the two structures is not adequate. Locking just one of the structures would provide no assurance that water users would not be tempted to increase the water flowing from their headgate and onto their crops. Both structures are locked throughout the irrigation season to ensure adequate control of the delivery system and efficiency in the operation of the system.

The Twin Falls Canal Company padlock inventory totals approximately 9,000 padlocks. All of these padlocks are out in the field year-round and exposed to the elements, therefore creating their own life span. If we can get 20 years out of a padlock, we only have to replace about 450 each year, resulting in approximately $9,000.00 annual expense just to keep the current inventory operational.

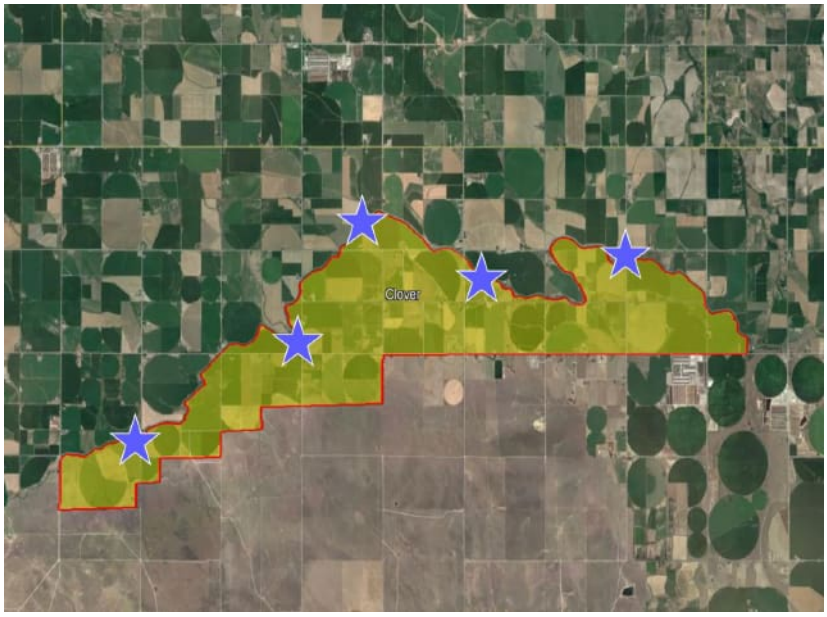
Q. HAVE YOU DEVELOPED ANY ADDITIONAL RE-REGULATING RESERVOIRS SINCE 2010?

A. Yes, we constructed the Kinyon Pond on the far west end of the Highline Canal south of Castleford in 2012-13.

Q. CAN YOU DESCRIBE HOW THAT POND WORKS AND WHAT IT DOES?

A. The Kinyon Pond was constructed to help the company overcome a very specific challenge to our ability to provide a high level of service to our Water Users, while protecting the capacity of the canal system and focusing on our efficiencies. There is a three-day travel time for water diverted at the head end of our canal system at Milner Dam that is destined to be delivered at the tail end of the system. In the past, many water users at the end of the canal system endured water supply shortages as a result of fluctuations that occurred within the system. When these fluctuations occurred, the tail end of the system dried up, and those Water Users would experience water a shortage for three days while water managers shuttled water through the system to restore flow to these users. Three days out of water is not acceptable and water managers were forced to carry extra water within the system if an effort to ensure that these Water Users at the end of the system continued to have water in spite of the inevitable fluctuations that can occur. The Kinyon Pond has a capacity of approx. 300AF of water and has been designed to provide water to these Water Users when these fluctuations occur. The Kinyon Pond capacity is filled early in the season when we experience wet cold periods and water demand suddenly drops, the facility then remains full and ready to supply the necessary flow to overcome the three-day travel time required to replace the water supply when fluctuations occur. Water managers then watch closely for a break in the weather or demand to identify their next opportunity to refill the capacity of the pond and be prepared and ready for the next event. Since the construction of the Kinyon Pond water managers no longer need to carry artificially high

flows within the system to ensure a consistent and reliable water supply to our water users at the end of the system. The pictures below show the Kinyon Pond.



Q. WHAT IMPROVEMENTS ARE BEING MADE AT THE CLOVER PROJECT?

A. The Clover Irrigation Pump Company represents approximately 4,000 acres on the south side of the company's High Line Canal. Being positioned on the south side of the High Line Canal means that the ground elevation of the Clover tract is higher than the water surface elevation in the High Line Canal, and all of the water delivered to Clover needs to be pumped out of the High Line Canal. The Clover tract has been in existence since the early 1900's and pumps water from the High Line Canal into a series of smaller, gravity flow canals where it is delivered to the 4,000 acres within the tract. In 2021 The Twin Falls Canal Company assisted

the Clover Irrigation Pump Company in securing an NRCS grant. The upgrade involved a three phase, five-year plan to replace the 100-year-old pump and 48-inch pipe that had served well past its life expectancy. The pump and pipeline are to be replaced with five new smaller pump stations feeding smaller pipes enroute to the end goal which is to pressurize the entire 4,000-acre tract. TFCC crews in 2022 completed the company's commitment to phase 1 of the project by installing two new diversion structures on the High Line Canal. To ensure accurate measurement at these new diversion structures, the company installed three new automated Rubicon Piko-Meters with the help of a cost shared grant from the Idaho Water Resource Board. The next two phases of the project will include three more diversion structures along with three more automated Rubicon Piko-Meters. The following map outlines the sites for the proposed five pumping plants and their general locations on the High Line Canal.

Q. WHAT CHANGES HAVE YOU NOTICED WITH REGARD TO CHANGES TO SPRINKLER IRRIGATION ON THE PROJECT?

A. When taking a quick look at the 1992 imagery available on Google Earth it is important to recognize the fact that there are virtually no circles on the Twin Falls Canal Company Tract. Over the course of the past 30+ years the conversion from gravity irrigation to sprinkler irrigation has consumed approximately 50-60% percent of the tract.

Commonly, sprinklers are considered to be much more efficient irrigation system than gravity irrigation, leading one to assume that less water may be required as acres convert to sprinkler. While on-farm efficiencies are no doubt improved, from a canal management perspective the opposite is true.

Historically under gravity irrigation, acres upon acres of ground was being furrow irrigated with sod ditches, concrete ditches and siphon tubes. In the past, under furrow irrigation, waste ditches existed at the end of every field and waste water was collected in these waste ditches and conveyed back into the canal system to be re-delivered to other down gradient acres on the project. This reuse of wasted water went a long way towards the efficiency numbers on the tract as we were able to deliver the same water to potentially 3, 4, maybe 5 or more different water users. Somewhere in the archives of historical information about the Twin Falls Canal Company a state engineer was quoted as saying that *"a drop of water is thoroughly exhausted by the time the Twin Falls Canal Company is through with it"*, referring to this ability to recapture waste water and re-deliver it again and again. With the conversion to sprinklers there is no longer waste water flowing off of those fields and available for reuse, but those downstream water users remain, who are still entitled to their water. We simply have to bring in more water into the

system to supply those needs instead of the way we historically provided much of that water as a result of the upstream neighbor's waste water.

Bringing "*more water into the system"* has never been considered a viable option, and in fact, system capacity precludes it. At maximum diversion rate in the heat of the summer the system is at its most vulnerable point. Freeboard on the systems main canals as well as all of the smaller delivery canals is minimal, and the capacity for more water simply isn't there. Instead, the Twin Falls Canal Company has implemented standard operating procedures within the company, and identified and implemented water efficiency practices and projects to ensure the company's ability to deliver consistent and reliable water delivery to all Twin Falls Canal Company shareholders.

Seep tile and tunnel returns continue to decline as sprinkler irrigated ground does not provide the same percolation into the shallow aquifers as gravity irrigated ground used to. It is also important to understand the engineering that went into the Twin Falls Canal Company canal system when it was originally constructed in the very early 1900s, and understand the relationship between the company's High Line Canal and the Low Line Canal. All acres irrigated from the High Line Canal (approx. 73,000 acres) waste back into the Low Line Canal allowing us to again recapture the water and re-deliver it to other down gradient acres on the tract.

Q. HOW MANY RETURN FLOW SITES ARE MONITORED ACROSS THE PROJECT?

A. Across the Twin Falls Canal Company System, 28 drains have been identified. These 28 drains make up the bulk of all of the waste water leaving the system into the Snake River. These drains are measured regularly throughout the irrigation season and the resulting measurements

are totaled and used to monitor and determine Twin Falls Canal System efficiencies at any given time. Typically, (for example) if we determine that the total sum of the return flow network is at a reasonably low level we know that the canal system is running pretty tightly. If we see that the total sum of the Return Flow Network is unreasonably high, we can determine that the canal system might be running loosely and we can use these measurements to identify areas within the tract where we need to tighten up to improve efficiencies.

Q. HAVE YOU NOTICED ANYTHING ABOUT RETURN FLOW TRENDS IN GENERAL?

A. End of the system returns to the Snake River have always been of particular interest to the water managers within the Twin Falls Canal Company. That being said we are always on a quest to reduce end of the system returns to the river. In system returns, or waste water returns that come off of individual farms or individual farm fields have historically been a big component of our overall water supply. Waste returns of this type have for decades returned to the canal system in a manner that allowed water managers to re-deliver the water, time and time again. Conversion to sprinkler irrigation on the project has altered the flow patterns of both of these types of returns. The in system returns that historically conveyed waste water through waste ditches and back into canal company facilities do not exist when conversion to sprinkler occurs. The inability to recapture and redeliver that waste water becomes a challenge for water managers to continue to provide water to those down gradient users that were supplied at least a portion of the water supply via these waste water returns. On the other side of the same conversation, after significant sprinkler installation, return flows to the Snake River can become much more volatile. As weather events occur during the irrigation season for example, a July or August rain or hail storm may cause many irrigators to turn off their sprinkler at the same time

resulting in sudden increases in waste water leaving the canal system and into the river. Much of this often happened historically as well but its much easier to shut off your pivot from your phone that it is to go out in the field and adjust your gravity irrigation set during a rain or hail storm. Power outages are another conversation completely as all sprinkler irrigation will shut off and completely over flow drainages until power is restored or canal adjustments can be made and the effect of those adjustments may take hour or even days to be realized. By the time the effects of those adjustments are realized, the event is history and water managers must scramble to reverse the effect of the adjustments and restore the waters supply.

Q. HOW MANY SHARES DO YOU DELIVER WATER TO?

A. We have issued 202,690.93 shares that are delivered through 24 different rides.

Q. DO SHAREHOLDERS ALWAYS HAVE 1 SHARE PER ACRE?

A. No, some shareholders may have less than 1 share per acre and others may have up to 1.5 shares per acre.

Q. HAVE YOU NOTICED NEW RESIDENTIAL DEVELOPMENTS IN TWIN FALLS COUNTY SINCE 2013?

A. Yes, mostly around the City of Twin Falls, along with other subdivisions around Kimberly, Filer, and Buhl.

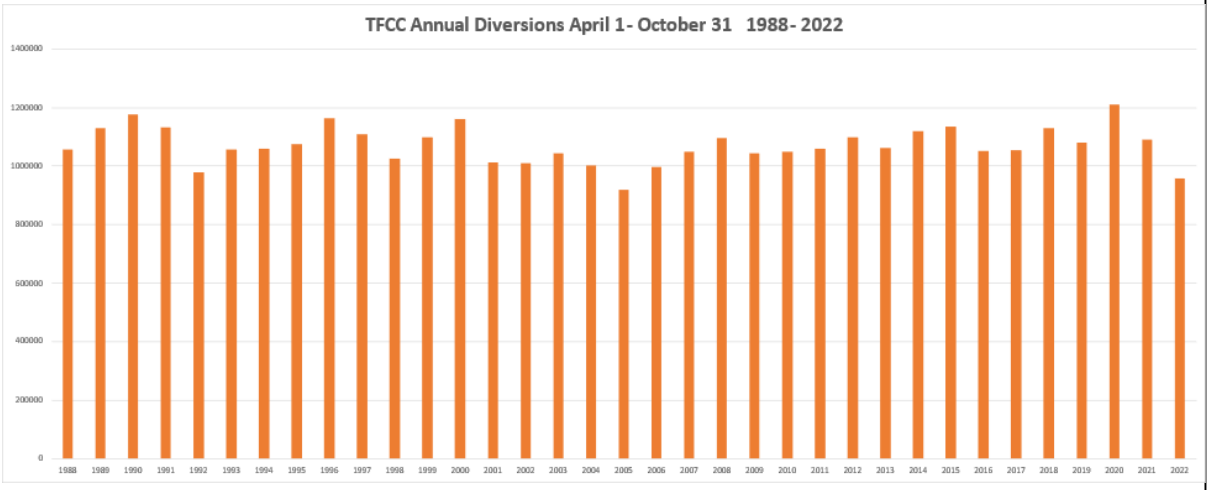
Q. DO THESE DEVELOPMENTS STILL RECEIVE SURFACE WATER FROM TFCC?

A. It is my understanding that the County and Cities require new developments to continue to receive surface water from TFCC through pressurized irrigation systems.

Q. DO YOU STILL DELIVER WATER UNDER THE SAME NUMBER OF SHARES?

A. To residential developments yes, however to certain commercial or industrial developments we may deliver less.

Q. DO SUBDIVISIONS REQUIRE THE SAME AMOUNT DELIVERY EVEN THOUGH LESS ACRES MAY BE IRRIGATED THAN BEFORE? HOW IS THE IRRIGAITON OPERATION DIFFERENT THAN A FARM?



A. Water use in new residential subdivision within the Twin Falls Canal Company project area are generally required, by the city they exist in, or by the County if they are in an unincorporated area to provide water within the subdivision via a pressurized irrigation (PI) station. Developers are required to install PI stations with any new development with full water shares, or one share per acre of developed land. New subdivisions plats often include large tracts of land, and plats consuming 40, 80, and sometimes over 160 acres have been in various phases of development for the past 20 years. Water use in residential subdivisions is very different than water use in the agricultural lands on the project. While a farmer has 160 shares on his 160 acres, the farmer is never watering the entire 160 acres at the same time, in fact, he is likely to have multiple different crops, all with different water needs, planted within his 160-acre farm. In a residential subdivision, all of the homes within the development have a sprinkler system installed to provide water to their lawns and ornamental spaces. Timers on those sprinkles systems are set for irrigation to occur at a time that is least disruptive to the lifestyles of the residents within the subdivision. It is very common for these PI stations to operate at a maximum diversion rate daily between the hours of 5:00 a.m. and 10:00 a.m. in the morning with little or no use the rest of the day, requiring a peak demand over and above peak delivery. This demand to delivery ratio requires storage capacity to work and even with significant storage capacity, low pressure issues create problems for the operators of the PI stations.

Q. IN YOUR OPINION IS THE COMPANY OPERATING AND DELIVERING WATER IN A REASONABLE MANNER?

A. In my opinion the Twin Falls Canal Company has always, and continues to set the bar in open canal operation. The Company, it's Management, and Board of Directors has always kept a keen eye on operations of the company, Maintenance of the system, and opportunities to improve our operations and delivery of water in any way possible.

Q. ANYTHING ELSE IN CONLCUSION?

A. Over the last 30 years the Twin Falls Canal Company's annual diversion rate has been right around 1,100,000 af per year. Some years just a bit higher and some years a bit lower but by and large 1,100,000 af. The Twin Falls Canal Company has adapted to the cropping pattern changes and the conversion to sprinkle in a manner that allows us to continue to provide a constant and reliable water supply to our water users while continuing to divert 1,100,000 af per year. I compiled Water District 01 data from 1988 through 2022 and created this graph below which to me does not show an increase in diversions over time.

As identified throughout this document, operating an open channel canal system efficiently is neither easy or inexpensive. The Twin Falls Canal Company has and will continue to make every effort to operate efficiently and constantly explore new ways and new opportunities to improve our canal system efficiencies.

Docket No. CM-DC-2010-001

FIFTH AMENDED FINAL ORDER REGARDING METHODOLOGY FOR DETERMINING MATERIAL INJURY TO REASONABLE IN-SEASON DEMAND AND REASONABLE CARRYOVER

Surface Water Coalition Expert Report

May 2023

Authors
David C. Colvin, P.G.
Erick Powell, Ph.D., P.E.

1. Introduction

This report presents the opinions of David Colvin and Erick Powell. We are groundwater experts who have been retained by the Surface Water Coalition (SWC) for issues being addressed in Docket CM-DC-2010-001. David Colvin is the primary author of this report, has 27 years of experience and is licensed as a Professional Geologist in Idaho. Erick Powell is a supporting author, has 17 years of experience and is licensed by the State as a Professional Engineer. Our resumes are included as Attachment A and B, respectively. We are basing our opinions on the information available at this time and reserve the right to alter our opinions should new or different information become available in the future.

On April 21, 2023, the Director of the Idaho Department of Water Resources (IDWR) issued the Fifth Amended Final Order Regarding Methodology for Determining Material Injury to Reasonable In-Season Demand and Reasonable Carryover (IDWR, 2023a, "Fifth Methodology Order") and the Final Order Regarding April 2023 Forecast Supply (IDWR, 2023b, "2023 As-Applied Order"). In the Fifth Methodology Order, the Director restated the nine steps prescribed by the methodology with updates to various aspects of the prediction of forecasted supply (FS), estimates of reasonable in-season demand (RISD), determination of the in-season demand shortfall (IDS), and determination of curtailment requirements. The Fifth Methodology Order requires curtailment for junior groundwater rights that:

- Do not have approved mitigation plans;
- Fail to secure the required water consistent with their approved mitigation plans; or
- Otherwise fail to comply with their approved mitigation plans.

The As-Applied Order predicts a 75,200 acre-foot (AF) IDS for the 2023 irrigation season, which will result in mitigation requirements or curtailment for groundwater rights with priority dates junior to December 30, 1953. Additional details of the IDS are presented as proportionate shares associated with various water user entities.

Summary of Opinions

Below is a summary of our opinions related to the information presented in the the Fifth Methodology Order and the 2023 As-Applied Order. Additional discussion is in the pages that follow.

1. The Eastern Snake Plain Aquifer Model (ESPAM) Version 2.2 is widely accepted as the best available scientific tool for evaluating regional Easter Snake Plain Aquifer (ESPA) hydrology, specifically the reach gain/loss impacts of curtailing groundwater pumping.
2. The use of the steady-state version of ESPAM is inappropriate for determining the priority date of a curtailment intended to mitigate in-season demand shortfalls (IDS), as required by the methodology. The steady-state version of ESPAM 2.2 has been demonstrated to overestimate the curtailment in-season benefits by more than an order of magnitude.

3. The transient superposition version of ESPAM 2.2 is the appropriate model type for calculating the in-season Snake River near Blackfoot to Minidoka reach gain benefits of curtailing junior groundwater pumping.
4. Regardless of the prior modeling approaches required, the Fifth Methodology Order correctly requires that transient modeling has to be used to calculate the in-season benefits of groundwater curtailment.
5. Transient groundwater modeling of the ESPA has been common practice for over a decade and is routinely utilized for evaluating the transient impacts of groundwater pumping on Snake River gains/losses.
6. The 2023 As-Applied Order utilizes a steady-state model to calculate the proportionate share of IDS that various entities are responsible for mitigating. These proportionate share amounts can only be met by direct delivery of surface water and are not relevant to understanding the benefits of groundwater curtailment.

2. Discussion of Opinions

a. ESPAM introduction

Groundwater modeling prescribed in the steps in the Fifth Methodology Order utilizes the Eastern Snake Plain Aquifer Model (ESPAM), originally known as the Enhanced Snake Plain Aquifer Model. ESPAM was developed and is maintained by IDWR staff. ESPAM development and updates are guided by the input of the Eastern Snake Hydrologic Modeling Committee (ESHMC), a multi-stakeholder group of scientists and engineers representing federal/state agencies and water users across the ESPA. (Sukow, 2021a)

ESPAM 2.2 is supported by the ESHMC and broader scientific community as representing the best available science for regional hydrologic analysis of the ESPA. The latest version of the model is ESPAM 2.2 which received approval from the ESHMC in 2021 and has been adopted for regional aquifer management planning and water rights analyses.

ESPAM 2.2 is an appropriate and reliable tool for the evaluation of regional hydrologic conditions and scenarios within the ESPA. Its use at local scales must be evaluated on a site-by-site basis to confirm that regional model generalizations, simplifications, and assumptions are appropriate for the local scale of the specific model scenarios being run. (Sukow, 2021a)

After transient calibration, IDWR created steady-state and transient superposition versions of ESPAM 2.2 for predictive analyses. Superposition models are generally created to represent hydrologic interactions within the aquifer in a way that allows for the isolation of model inputs so that their impacts are not conflated with other changes in the system. (Sukow, 2021c) IDWR ran scenarios using a previous version of ESPAM comparing the transient superposition model to the fully populated model that represents monthly inputs for the calibration period. The transient

superposition model showed minimal differences compared to the fully populated model. (Sukow, 2012)

Steady-state models depict equilibrium conditions with no change through time. They are best used to evaluate the ultimate impact of a change, without regard to time. The steady-state superposition version of ESPAM 2.2 consists of a single stress period with average hydrologic inputs.

Transient models allow model inputs and outputs to vary with time and can represent changing hydrologic conditions. The transient superposition version of ESPAM 2.2 has monthly stress periods with average hydrologic inputs from the calibration period of 1980 to 2018. This model allows for many years of predictive calculations while representing the seasonal fluctuations in hydrologic model inputs and outputs. (Sukow, 2021c)

b. ESPAM Curtailment Analysis

During the development of ESPAM 2.2, IDWR utilized the superposition versions of the model to calculate the impacts of various curtailment dates as a demonstration of appropriate model use for regional hydrologic analysis. The curtailment analyses calculated the changes to spring flow and Snake River gains/losses due to the curtailment of groundwater pumping for five different priority dates. The ESHMC reviewed these model runs and approved the associated report in 2021 (Sukow, 2021c).

OPINION #1: ESPAM 2.2 is widely accepted as the best available scientific tool for evaluating regional ESPA hydrology, specifically the reach gain/loss impacts of curtailing groundwater pumping.

c. Methodology Technical Working Group

During November and December of 2022, IDWR convened a Technical Working Group (TWG) to provide input on potential changes to the Fourth Methodology Order (IDWR, 2016). The TWG consisted of technical experts and legal representatives for the SWC, IGWA, and other stakeholders. IDWR presented various potential changes to the methodology, including a November 28, 2022 presentation comparing the steady-state and transient superposition versions of ESPAM 2.2 for curtailment analysis. (Sukow, 2022)

In this presentation, Jennifer Sukow (IDWR) used 2022 curtailments ordered under the methodology to demonstrate the differences between transient model calculations for in-year, in-season increases for the Snake River near Blackfoot to Minidoka (nBF-M) reach gains compared to steady-state model calculations representing ultimate reach gains without regard to any realistic time frame.

Utilizing the steps detailed in the Fourth Methodology Order, the April Demand Shortfall forecast

was predicted to be 162,600 AF. As prescribed by the Fourth Methodology Order, the steady-state simulation of curtailment to December 25, 1979 resulted in an increase in nBF-M reach gains sufficient to mitigate the 162,600 AF Demand Shortfall. The use of the steady state model essentially represented the reach gain impacts over infinite time.

The same curtailment date used in the transient model resulted in an increase of only 16,200 AF of nBF-M reach gains from May through September 2022. This result is less than 10% of the April 2022 Demand Shortfall.

This pattern of steady-state responses significantly over-estimating the in-season benefits of curtailment is also demonstrated at other curtailment dates, as shown in **Figure 1** below.

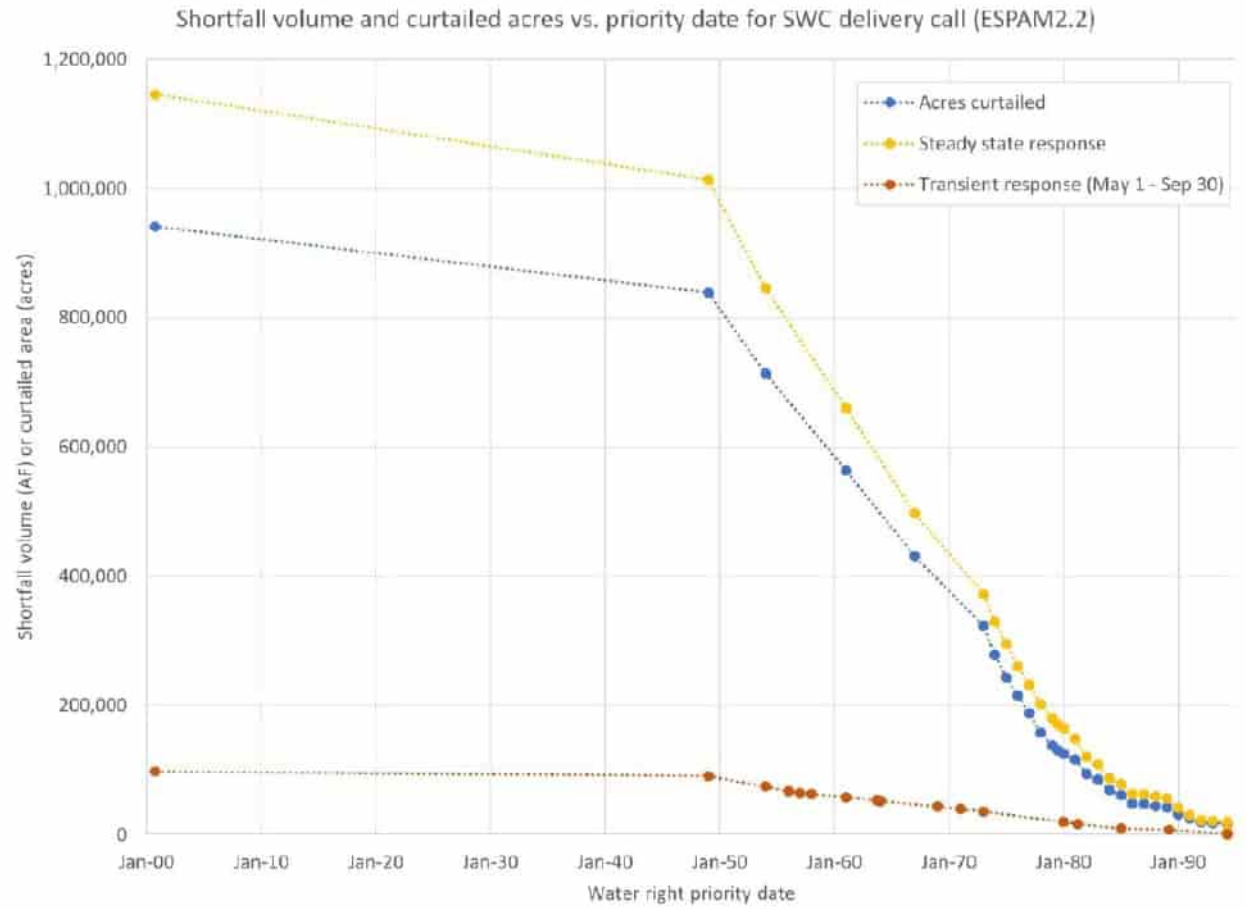

Figure 1 - Steady-State and Transient Model Response for Different Priority Dates (adapted from Sukow, 2022)

In her presentation slides, Ms. Sukow concluded the following:

- *"Steady state simulations are appropriate for evaluating the impact of aquifer stresses that have been applied for decades (i.e. groundwater pumping, continuous curtailment to same date every year)*

- *Transient simulations are appropriate to evaluate the impacts of aquifer stresses applied for short periods of time (i.e. short term curtailments with varying priority dates)*
- *Steady state simulations of continuous curtailment do not simulate the short term curtailments prescribed in the SWC methodology*
- *Transient simulations better simulate the short term curtailments prescribed in the SWC methodology"*

We agree with these conclusions.

OPINION #2: The use of the steady-state version of ESPAM is inappropriate for determining the priority date of a curtailment intended to mitigate In-season Demand Shortfalls (IDS), as required by the methodology. The steady-state version of ESPAM 2.2 has been demonstrated to over-estimate the curtailment benefits by more than an order of magnitude.

OPINION #3: The transient superposition version of ESPAM 2.2 is the appropriate model type for calculating the in-season Snake River near Blackfoot to Minidoka reach gain benefits of curtailing junior groundwater pumping.

d. Fifth Methodology Order Groundwater Modeling Topics

On April 21, 2023, the Director of IDWR issued the Fifth Methodology Order (IDWR, 2023a). The Fifth Methodology Order Conclusions of Law provide the legal requirements that must be met by the Methodology steps to protect the senior priority surface water rights in time, place, and quantity. Any identified Demand Shortfall must be mitigated in-season. If curtailment of junior groundwater pumping is the mitigation method, the short term results of curtailment need to be predicted in-season, within months of implementation.

The in-season time considerations of the Fifth Methodology Order are a critical consideration of the supporting modeling steps, and why a transient model must be used. Findings of Fact #84 provides a clear description of why a steady state model is inappropriate for the Methodology requirements of determining the in-season reach gain impacts of curtailment. Findings of Fact #89 justifies the use of a transient model.

The steady-state model curtailment results have been clearly demonstrated to be in grievous error. No credible scientific assertion can justify the use of steady-state model to meet the requirements of the Methodology because a steady-state model cannot calculate in-season curtailment benefits. The Fifth Methodology Order's transient modeling requirement is a much more accurate representation of reality.

OPINION #4: Regardless of the prior modeling approaches required, the Fifth Methodology Order correctly requires that transient modeling has to be used to calculate the in-season benefits of groundwater curtailment.

Transient groundwater modeling is not a novel idea, having been implemented by IDWR and the water user community routinely for a decade or more. ESPAM 2.1 was approved in 2013 with a calibrated transient version utilizing monthly stress periods, similar to ESPAM 2.2. Since at least 2013, the transient version of ESPAM has been used by IDWR and the water user community to evaluate the impacts of transferring ESPA groundwater rights (IDWR, 2022). In these transfer modeling scenarios, ESPAM is used to calculate the transient impacts to Snake River reach gains/loses, similar to the curtailment benefit analyses described above.

IDWR has also developed a groundwater model for the Big Wood River alluvial aquifer system. In the 2021 administrative hearing, use of the transient version of the model was required for evaluation of in-season changes to pumping stresses.

OPINION #5: Transient groundwater modeling of the ESPA has been common practice for over a decade and is routinely utilized for evaluating the transient impacts of groundwater pumping on Snake River gains/losses.

e. 2023 As-Applied Order Groundwater Modeling Topics

On April 21, 2023, the Director of IDWR issued the 2023 As-Applied Order (IDWR, 2023b). The 2023 As-Applied Order determined a SWC forecasted supply with a 75,200 AF IDS. Utilizing the transient modeling analysis prescribed in the Fifth Methodology Order, a curtailment date of December 31, 1953 was identified as providing an increase in nBF-M gains sufficient to mitigate the IDS.

The 2023 As-Applied Order also presents a steady-state analysis of the proportionate share of the IDS. The analysis intended to associate the percentage of the IDS that water user entities were responsible for, thereby identifying the amount of IDS they are responsible for mitigating. The rationale for this approach is that the IDS represents the legacy impacts of many decades of groundwater pumping. The use of the steady-state version of ESPAM 2.2 is premised on the assumption that the aquifer, groundwater pumping, and other hydrologic model inputs are all at equilibrium conditions. While this is not accurate or true, it may be an acceptable simplification of the system because it likely does not lead to unacceptable errors when calculating the proportionate shares of specific water user entities.

IDWR's use of the steady-state model to represent decades of legacy pumping impacts highlights the multi-year challenge of protecting senior SWC water rights.

However, the proportionate share mitigation requirements identified needs to be limited to mitigation with direct delivery of surface water. Because the proportionate shares are determined using a steady-state model, they have no bearing on IDS mitigation with groundwater curtailment of the various water user entities.

OPINION #6: The 2023 As-Applied Order utilizes a steady-state model to calculate the proportionate share of IDS that various entities are responsible for mitigating. These proportionate share amounts can only be met by direct delivery of surface water and are not relevant to understanding the benefits of groundwater curtailment.

3. Groundwater Modeling Summary

Both the Fifth Methodology Order and 2023 As-Applied Order appropriately utilize the best available tool for evaluating ESPA hydrology, ESPAM 2.2. The evaluation of curtailment benefits requires the use of a transient model because of the in-season mitigation or curtailment requirements of the Fifth Methodology Order. The steady-state version of ESPAM 2.2 grossly exaggerates the benefits of curtailment for in-season mitigation and is inappropriate for determining a curtailment priority date. Because it uses the steady-state version of ESPAM 2.2, the proportionate share analysis presented in the 2023 As-Applied Order can only be used to determine the amount of surface water a water user entity could provide as mitigation of their portion of the IDS. The proportionate share analysis has no relevance to evaluating groundwater curtailment benefits.

Dave is a Principal Hydrogeologist and Senior Project Manager with over 25 years of experience in groundwater hydrology, water resources, and environmental sciences. He supervises teams of diverse subject matter experts and provides technical leadership to solve today's water resource challenges. Dave serves as the Groundwater Team Leader responsible for managing staff, resources, projects and clients for a group of hydrogeologists. His technical expertise subject areas include water supply development, groundwater management, groundwater governance/administration, surface water/groundwater interaction, riverbank filtration (RBF), soil aquifer treatment (SAT), managed aquifer recharge (MAR), aquifer storage and recovery (ASR), aquifer characterization, groundwater modeling, and subsidence caused by groundwater pumping.

FEATURED PROGRAM & PROJECT EXPERIENCE

Surface Water Coalition, Idaho (2019-ongoing)

Lead Hydrogeologist and Project Manager providing litigation support related to water management of the Eastern Snake Plain Aquifer. Provides protection of surface water flows and senior surface water rights from negative impacts due to junior groundwater pumping. Serves on the Eastern Snake Plain Hydrologic Modeling Committee supporting MODFLOW modeling activities related to complex surface water/groundwater management and water rights administration. Also serves as the SWC representative on technical working groups guiding the implementation and adaptation of a settlement agreement between the SWC and Idaho Ground Water Appropriators including monitoring/evaluation of hydrology, pumping reductions, consumptive use and planning for managed aquifer recharge.

Salt River Project – Gila River Basin Adjudication, Arizona Superior Court Case W1-103, San Pedro Basin, AZ (2018 – ongoing)

Hydrogeologist providing groundwater analysis and modeling supporting adjudication of water rights in the San Pedro Basin. Tasks include oversight of groundwater model development, calibration and uncertainty analysis, and trial/litigation support. Provides protection of surface water flows, riparian habitat, and water rights from negative impacts due to groundwater pumping.

City of Aurora – Horizontal Well Project; Weld County, CO (2019 – ongoing)
Project Manager for feasibility evaluation and planning of two radial collector wells for the City's Prairie Waters System. The project targets increasing system yield while maximizing riverbank filtration water quality improvements. Investigation included hydrogeophysical surveys, exploratory drilling, aquifer testing, and groundwater modeling. Results included design of horizontal wells that maintain the existing system water quality while providing adaptable system operations that can increase yield during drought demands. Currently the Lead Hydrogeologist providing design phase services.

City of Northglenn – ASR Feasibility Evaluation and Pilot Testing (2020 – ongoing)
Lead hydrogeologist and Project Manager for feasibility investigation and pilot test system design services. Support includes ASR feasibility data analysis, water quality evaluation, DWR and EPA UIC permitting, pilot system design and test planning. The project will provide pilot storage of the City's fully consumable water rights, providing more surface storage space for other supplies. If recovered water quality is compatible, the pilot system will be converted into permanent infrastructure as the first phase of a larger ASR system.

Riverence Holdings LLC – Snake River Spring Supply Support (2022-ongoing)
Project Manager and lead hydrogeologist supporting multiple fish hatcheries throughout Idaho's Magic Valley. Provides hydrogeologic planning of spring fed aquaculture focusing on upgradient aquifer pumping and recharge impacts on water rights, water quality, and water supply reliability.

City of Aurora – Box Elder Basin Aquifer Storage and Recover (ASR) Feasibility Investigation and Pilot Testing (2018 – Ongoing)
Project Manager and lead hydrogeologist investigating the feasibility of recharging and storing water in the Box Elder alluvial aquifer at the Aurora Center for Renewable Energy (ACRE). Tasks included hydrogeophysical surveys, exploratory drilling/test pits, and infiltration testing. The project identified recharge as a viable option for innovative storage opportunities and has moved into a pilot test planning phase. Current services include recharge source water characterization, water rights and permitting planning, water quality evaluation, groundwater modeling, and pilot system design.

Dominion Water and Sanitation District – Groundwater Support; Douglas County, CO (2015-ongoing)
Lead Hydrogeologist providing Denver Basin and South Platte alluvial aquifer groundwater resources planning services including water rights evaluation, water quality assessment, well field yield estimation and project planning. Provided hydrogeologic and contractor management support during Denver Basin well site design, construction, testing, aquifer characterization, and sampling. Additional technical support included documentation for County hearings, interactions with local water agencies, and groundwater transaction due diligence.

Town of Erie – Water Supply Planning Support (2018 – ongoing)
Lead hydrogeologist and Project Manager providing groundwater support related to water supply planning. Services include aquifer characterization, water quality studies, horizontal directionally drilled well field design, ASR feasibility analysis, and water rights. Prepared Colorado Water Conservation Board and Division of Local Affairs grant applications to obtain project funding. The project will provide a 3,000 GPM expansion of the Town's water supplies.

Town of Castle Rock – Groundwater Support; Douglas County, CO (2015-ongoing)

Project Manager providing comprehensive groundwater support. Projects have included:

- Denver Basin Well Drilling, Testing, and Aquifer Storage and Recovery (ASR) – Support includes Denver Basin ASR planning/permitting, bidding services, contractor management, construction oversight, well/pump design, aquifer testing, and groundwater regulatory support.
- Alluvial Well Field Expansion and Rehabilitation – Project Manager for two projects aimed at improving yields in well fields affected by biofouling and performance issues. Oversaw construction and testing of six horizontal directional drilled (HDD) wells installed to increase yield, performance, and sustainability.
- City of Aurora and Town of Castle Rock – Lost Creek Underground Storage Pilot Project; Lost Creek Designated Basin, CO (2017-2018)
- Project Manager for aquifer characterization and evaluation of recharge potential for underground water storage pilot project. Obtained grant funding and facilitated multiple stakeholder project planning and implementation. The project identified important field investigation methods and results for storage related aquifer characteristics previously overlooked in desktop studies.

City of Aurora – Prairie Waters North Campus Master Plan; Adams and Weld Counties, CO (2017-2019)

Lead hydrogeologist providing master planning services for approximately 20 MGD expansion of the Prairie Waters Project – North Campus over the next 20 years. Facility expansion included riverbank filtration well field, pipelines, and storage reservoirs. Led facilities operational planning, supported water resource planning, gap analysis, and capital improvements planning.

Denver Water – Aquifer Storage and Recovery (ASR) Pilot Project, City and County of Denver, CO (2016-current)

Groundwater technical support and project management for ASR feasibility investigation. Provided Denver Basin aquifer characterization including exploratory borehole drilling, hydrogeophysical investigation (Nuclear Magnetic Resonance and conventional methods), and 3-D geologic modeling. Current services include an advisory role for installation of a multi-aquifer Westbay Denver Basin monitoring well.

City of Greeley – ASR Feasibility Evaluation (2019-2021)

Senior Technical Advisor for a project evaluating the feasibility of new and existing ASR projects in multiple bedrock aquifers. Includes evaluation of water quality, aquifer characteristics, well construction/testing, project planning, and regulatory support, including negotiating an EPA UIC Rule Authorization in less than two months.

Colorado Water Conservation Board - HB16-1256 South Platte Storage Study; CO (2018)

Lead hydrogeologist providing evaluation of underground water storage options for the Lower South Platte alluvial aquifer. Provided alluvial storage site evaluation, conceptual design, cost estimates, and comparison to surface storage options.

Aurora Prairie Waters Project – North Campus; Weld County, CO (2008)

Supported City of Aurora's Prairie Waters project near the South Platte River, CO. Acted as team liaison for multi-consultant, multi-disciplinary project team. Field investigation and construction tasks included field

oversight of drilling, well construction, pump/motor installation, aquifer testing, system start up testing, well field yield optimization, and geotechnical investigations. Support also included the design, construction, and operation of alluvial recharge and riverbank filtration pilot test facilities. Developed and implemented pilot test procedures, including tracer studies to assess flow paths, travel times, and stream/aquifer interaction. MODFLOW modeling support for the Prairie Waters Project included development of regional groundwater model for Colorado Division 1 case 2006CW104. Performed parallel processing model calibration using UCODE. Prepared expert and rebuttal reports, exhibits and materials used in settlement negotiations.

Eagle River Water and Sanitation District and Upper Eagle Regional Water Authority – Groundwater Support; Eagle County, CO (2010-ongoing)

Project Manager and lead Hydrogeologist for alluvial well field groundwater support. Projects have included:

- GWUDI Evaluation – Regulatory support, groundwater modeling and operational monitoring of alluvial well fields in support of CDPHE GWUDI evaluation
- Lake Creek Well Field Planning – Services included groundwater modeling, well drilling, aquifer testing, source water quality characterization, regulatory support for Eagle County 1041, CDPHE, and DWR permitting
- Well field maintenance and rehabilitation support – well rehabilitation in response to well issues including pump issues, casing holes, and water quality contamination

Dominion Water and Sanitation District – Groundwater Support; Douglas County, CO (2015-ongoing)

Denver Basin groundwater supply planning services including water rights evaluation, water quality assessment, well field yield estimation and project planning. Technical support included documentation for County hearings, interactions with local water agencies, and groundwater sale transactions.

City of Steamboat Springs – Infiltration Gallery System Expansion; Routt County, CO (2018-ongoing)

Project Manager for feasibility evaluation of alluvial groundwater supply expansion alternatives. Expansion options being considered include vertical and horizontal well options. Tasks included exploratory drilling, aquifer testing, groundwater modeling and conceptual expansion system design. Modeling was performed to optimize well siting to maximize yield, maintain water quality, and to minimize pipeline costs.

Texas Water Development Board – Statewide Subsidence Risk Evaluation (2018)

Technical advisor for risk evaluation of subsidence due to groundwater pumping in all Texas major and minor aquifers. The project used well lithology data with model predicted water level declines to create a statewide risk map and prioritized table. Recommended follow up actions for identified areas of risk. The project provided important subsidence risk information for statewide planning and local user considerations.

Village at Taos Ski Valley – Spring Water Supply Expansion; Taos County, NM (2018-ongoing)

Senior Technical Advisor providing groundwater evaluation into the management, protection and expansion of spring water supplies.

City of Phoenix – ASR Tracer Test Design; Maricopa County, AZ (2017)
Provided MT3D groundwater modeling to assist in aquifer characterization, travel time estimates, and the design of an ASR tracer injection test for feasibility. The testing was in support of the Northeast Phoenix Reclaimed Water Recharge and Recovery Study. The system is intended to create a potable water resource through Indirect Potable Reuse (IPR), provide additional non-potable supplies, and to mitigate land subsidence issues.

Groundwater Relief – Kutupalong Refugee Camp Groundwater Supplies; Cox's Bazaar, Bangladesh (2019)
Volunteer hydrogeologist providing well testing and water quality support to field geologists. The project is developing emergency water supplies for nearly 1 million Rohingya refugees who have fled religious persecution in Myanamar.

City of San Angelo – Riverbank Filtration Feasibility Evaluation; Tom Green County, TX (2018)
Provided feasibility evaluation, preliminary siting, design and costs for a potential riverbank filtration (RBF) well field near the Concho River. This information was used to evaluate RBF as an alternative for expansion of the City's water supply.

Tarrant Regional Water District – Cedar Creek Wetlands; Kaufman County, TX (2013)
Project manager and lead Hydrogeologist for riverbank filtration feasibility investigation along the Trinity River. Project tasks include geotechnical, hydrogeologic, and surface geophysical surveys, groundwater modeling, and design, construction and testing of riverbank filtration pilot test sites.

Rangen, Inc. – Water Rights Support; Gooding County, ID (2010-2016)
Expert witness providing testimony and trial support for a water rights hearing (IDWR Case No. CM-DC-2011-004) involving springs and complex surface water/groundwater interaction of the Eastern Snake Plain Aquifer. Represented a fish hatchery reliant on spring flow that was being impacted by groundwater pumping. Served on the Eastern Snake Plain Hydrologic Modeling Committee supporting MODFLOW modeling activities in the Eastern Snake Plain of Idaho.

Overturf, McGath, and Hull, P.C. – Stewart No. 1 Ditch Company; Pitkin County, CO (2017)
Expert witness support including expert and rebuttal reports, depositions, and settlement negotiations for a civil case involving alleged roadway water damage from ditch operations.

Fredrickson Law Offices – In-Play Golf; Weld County, CO (2017)
Expert witness providing expert and rebuttal reports, depositions, and trial support for a civil case involving alleged water damages from golf course irrigation.

Boulder Valley School District – Douglass Elementary Non-Tributary Well Support; Boulder County, CO (2018)
Project Manager for a non-tributary well application in the Boulder Complex Area of the Denver Basin Aquifers. Provided aquifer characterization and regulatory support leading to a non-tributary determination and permit approval.

Boulder County Parks and Recreation – Kenosha Ponds Groundwater Evaluation; Boulder County, CO (2016)
Expert witness providing hydrogeology water rights support for a Boulder County Parks and Recreation augmentation pond. Technical support included expert report writing and trial exhibit preparation for the hydrologic characterization of a recharge pond between two streams where the pond bottom was below the water table.

City of Burkburnett, Texas – Alluvial Well Field Evaluation; Wichita County, TX (2016)
Project Manager and groundwater lead for evaluation of underperforming well fields near the Red River. Wells ranged from 3-50 years old with a variety of issues causing low yields. Project tasks included well operational data integration, analysis, and development of alternatives to improve well yields.

Penrose Water District – Arkansas River Alluvial Well Field; Fremont County, CO (2016)
Groundwater technical management for planning, design, and construction of an alluvial well field for diversion of Arkansas River water rights. Tasks included aquifer characterization, water rights support, groundwater modeling, contractor management, well drilling, construction and testing.

Salt River Project – New River Agua Fria Underground Storage Project; Phoenix, AZ (2013)
Project involved optimization and in-channel expansion design for an existing recharge facility. Support included evaluation of operational data and adaptation of an existing MODFLOW model for operational optimization and feasibility testing.

City of San Marcos, Texas – Well Performance Investigation and Replacement Plan; Hays County, TX (2015)
Project Manager and groundwater lead for investigation into reduced yield problems for a well in the Edwards Aquifer. Well construction and operational data were analyzed to test viability of rehabilitation or equipment replacement. Provided ultimate solution of siting a replacement well in a more productive aquifer area.

Oakwood Homes – Neighborhood Scale Dewatering Systems and Water Rights; CO (2016)
Project Manager and groundwater lead for planning, design, and permitting of neighborhood scale dewatering systems. Managed project work including groundwater modeling, system design, data analysis, contractor coordination, DWR and CDPHE permitting, and water rights evaluations.

Winkler Services – Well Field Siting and Design; Wink County, Texas (2017)
Technical advisor for well field siting in the Pecos Valley Alluvium and Upper Dockum Aquifer. Support included project planning, aquifer characterization, and geologic modeling.

Donala Water and Sanitation District – Reuse Evaluation; El Paso County, CO (2015)
Preliminary feasibility investigation into riverbank filtration alternatives for indirect potable reuse. Evaluated hydrogeologic conditions for permitting, cost, and performance feasibility considerations.

Confidential Client; Groundwater Supply and Subsidence Analysis; AZ (2011)
Development of regional MODFLOW models used to estimate well field yield and land subsidence due to groundwater pumping in Arizona. Work included statewide study of subsidence-related empirical

relationships and prediction methods, aquifer characterization, 3-D geologic and groundwater flow modeling, automated model calibration and predictive uncertainty analysis using PEST, and numerical MODFLOW subsidence modeling.

City of Scottsbluff – Well Field Uranium Investigation and Monitoring; Scotts Bluff County, NE (2016)

Technical advisor for a project aimed at reducing uranium concentrations in an alluvial groundwater supply. Provided aquifer characterization and uranium monitoring data analysis.

Confidential Client - Oilfield Produced Water Infiltration Modeling, San Louis Obispo County, CA(2010)

Lead Hydrogeologist for the development of an engineering design MODFLOW-SURFACT model with the goal of infiltrating 13 acre-feet of water per day into the subsurface of a 200 acre alluvial site. Performed model calibration using PEST software in a parallel processing environment utilized 50 geologic conceptualizations for stochastic predictions of system performance.

CDPHE – Summitville Superfund Site; Summitville, CO (2008)

Provided support for abandoned mine hydrology and geochemistry, field sampling, monitoring and mine facility inspection, and database support. The project goal was to monitor and minimize mine waste impacts on the Alamosa River.

Various Mines – Groundwater Modeling and Analysis; Basin and Range Province; NV (2010)

Provided MODFLOW modeling and water balance studies in support of mine water management and regulatory reporting. Analyses included point flow surface water modeling to evaluate stream gain/loss; detailed water balance quantifications; well inventories and pumping estimates; groundwater underflow assessments.

Miron Construction - Laramie-Fox Hills Well; Hudson, Colorado (2008)

Assisted in design and field engineering for the construction and testing of a 960-foot deep, large capacity, municipal/industrial, Laramie-Fox Hills water supply well at the Hudson Correctional Facility.

Perini/US Army Corps of Engineers – Groundwater System Design and Optimization; Baghdad, Iraq (2007)

MODFLOW modeling support for the U.S. Agency for International Development in Baghdad, Iraq. Developed a numerical groundwater model for the optimization of water supply well locations and pumping operations. Main objectives were to maximize well yields while minimizing differential land subsidence across newly constructed East End Barracks.

Colorado Haiti Project (Volunteer Position); Petit Trou de Nippes, Haiti (2013)

Technical advisor for groundwater development, management, and protection in a rural, developing area of Haiti.

Water For People Groundwater Management Project (Volunteer Position); San Pedro Sula, Honduras (2008)
Technical advisor for development of a scope of work for a participatory groundwater management plan aimed at restoring and protecting an over utilized alluvial aquifer in a developing region.

ASARCO - California Gulch Superfund Site; Leadville, Colorado (2000-2005)
Conducted environmental sampling for the Kids First Program to identify and address sources of lead exposure for children in residential areas. Provided statistical analysis and reporting for evaluation of program effectiveness. Designed sampling plan and performed soil sampling and analysis to delineate extent of metals contamination at the Arkansas Valley Smelter Operable Unit. Provided technical support for hydrogeological and geochemical characterization of the Apache Tailings site; and implemented the surface water and groundwater performance monitoring program to assess the effectiveness of the remedial action. Conducted synoptic surface water flow measurement and water quality sampling.

Asarco - Omaha Lead Site, Omaha, Nebraska (2003)
Assisted in the development of program to identify sources of lead exposure for children in residential areas.

Mine Waste and Tailings Pile Sites, Various Locations (2000-2004)
Performed hydrologic evaluation of remedial alternatives for repository evaluation using Hydrologic Evaluation of Landfill Performance (HELP) model.

Industrial Groundwater Contamination Sites, Various Locations (2000-2005)
Performed groundwater modeling to assist design of groundwater extraction remediation wells using MODFLOW modeling code.

EPA - Vasquez Boulevard and Interstate 70 Superfund Site, Denver, Colorado (2002)
Designed, directed, and performed environmental sampling for project intended to identify sources of lead and arsenic exposure for children in residential areas.

Hertz Rent-a-Car - Former Underground Storage Tank, Colorado Springs, Colorado (2002)
Project Hydrogeologist and technical lead for the characterization, monitoring, and remediation of hydrocarbon contaminated soils and groundwater at a former underground storage tank site. Performed quarterly monitoring and reporting; developed and implemented an in-situ chemical oxidation remediation program.

R&R Super Service - Former Underground Storage Tank, Arvada, Colorado (2002)
Project Manager and technical lead for the characterization and remediation of soils and groundwater contaminated by petroleum hydrocarbons at a former service station. Responsibilities included client and regulatory interaction; site characterization activities to delineate the nature and extent of contamination in soil and groundwater; modeling of vapor and mass extraction rates using VENT2D; respirometry testing to quantify biodegradation rates in vadose zone soils; startup testing; operating, maintaining, and monitoring of an air sparge/soil vapor extraction system.

City and County of Denver - Former Stapleton International Airport Remediation; Denver, Colorado (2000)
Served as a hydrogeologist conducting field investigations to define nature and extent of hydrocarbon contamination and to determine remediation. Field tasks included lithologic logging with a hollow-stem auger and direct-push drilling rigs; soil, groundwater, and soil vapor testing, remediation system construction/operation/maintenance, data evaluation and reporting.

National Park Service – Mt. Rainier National Park, Longmire, Washington (1996-1997)
Biologist and crew leader for aquatic ecosystem studies in Mt. Rainier National Park. Conducted field surveys and sub-alpine wetland monitoring. Performed aquatic field sampling, wetland classification, biological species identification, and aquatic laboratory analyses.

Education

Ph.D. The Ohio State University Agricultural Engineering 2006
Advisor: Dr. Andrew D. Ward
Title: *Evaluating geomorphology and water quality of channel-forming discharges in Ohio headwater streams*

MS Brigham Young University Civil and Environmental Engineering 2002
Advisor: Dr. E. James Nelson
Title: *Bathymetry delineation and data collection preparing a CE-QUAL-W2 model on Scofield Reservoir, Utah*

BS Brigham Young University Major: Civil and Environmental Engineering 2001
Minor: Agronomy

Professional Experience

Project Engineer 2006 - Present
Brockway Engineering, PLLC
Twin Falls, Idaho

Project Engineering on hydrologic and hydraulic engineering design tasks, including: well design, well construction, well testing, water rights, water right transfers, pipeline design, water distribution systems, stream channel evaluation, floodplain assessment, irrigation water demand, and potable water demand.

P.E. Registrations in Idaho (13592), Utah (4859937-2202), Nevada (028772) and Oregon (91026)

Graduate Research Assistant 2002 - 2006
Department of Food, Agricultural, and Biological
Engineering The Ohio State University, Columbus, Ohio

Research consisting of: 1) evaluation of channel forming discharges, 2) two-stage channel design procedures, 3) nutrient performance within two-stage agricultural channels, and 4) theoretical nutrient spiraling under restored riparian projects.

Areas of Expertise

Groundwater modeling, flood plain evaluations, stream bank restoration and protection, surface water quality modeling, and water right transactions. Numerical groundwater flow simulations using FEMWATER, MODFLOW, and Groundwater Modeling System (GMS).

Professional Associations

American Society of Civil Engineers (ASCE)
American Ecological Engineering Society (AEES)
American Society of Agricultural and Biological Engineers (ASABE)
American Society for Engineering Education (ASEE)
Alpha Epsilon (ASABE Honor Society)

A. Evaluation of TFCC Project Acres

The project irrigated area for TFCC utilized in the Fifth Methodology is 194,732 acres. This figure is based on detailed aerial photo inspection and a delineation created by TFCC consultants in 2013. The acreage decreed in the Snake River Basin Adjudication is 196,162 acres. IDWR performed independent delineations in 2011 and 2017 in the course of developing its "irrigated lands dataset." This work involved manual inspection of aerial photography. Shapefiles developed from the 2011 and 2017 work indicate irrigated areas of 179,486 acres and 180,956 acres, respectively, or about 7 to 8% less than the 2013 acres used in the Fifth Methodology.

Raster files were provided by IDWR and shape files were created using ArcMap. The shape files were intersected with the 2013 acres to create shape files representing the difference between the two delineations. The 2011 and 2017 difference shape files were nearly identical. The 2017 difference shape file is shown in Figure 1.

Inspection the difference shape files reveals that the primary reason for the irrigated area difference is the removal of the following categories of areas: Ditches and ponds, fields that are apparently unirrigated, pivot corners, developed areas around the fringe of municipalities, and roadways.

Numerous factors influence the determination of acreage within a large canal company where shareholders operate independently from the company in terms of irrigation practices:

1. Ditches, ponds, or other waterways, whether private or company-owned, represent real evaporative and evapotranspirative demands on the system, just as much as irrigated lands. Water must be diverted from the river in order to meet these operational demands.

2. Fields are not irrigated every single year. Fields that look unirrigated one year may be irrigated the next year and may have been left idle due to a limited water supply and the desire to use available water on a higher value crop. And some lands which appear unirrigated may actually be lightly irrigated. An example of this potential error is illustrated in Figure 2, which shows a portion of the service area west of the City of Twin Falls in which clearly-irrigated fields were excluded from the 2017 delineation.

3. An aerial photo represents only a snapshot in time. Fields that look unirrigated in the snapshot of an aerial photo may actually be irrigated that year (for example, the photo may have been taken prior to planting or after harvest).

4. Development of an agricultural parcel into a residential area cannot be assumed to reduce the water demand. For example, a 40-acre parcel with 40 canal shares might be developed into a parcel containing 20 acres of actual irrigation after subtracting rooftops and hardscape. However, the 40 shares are still appurtenant to the parcel and the company is obligated to deliver them. Furthermore, the residential development will very likely have a peak demand at least as large as the previous agricultural use even though the irrigated acreage is less, due to the nature of small residential systems.

5. Many growers will double-crop, or may leave acreage fallow and put water on other land at the same on-farm efficiency. This can frequently occur when land is not fully covered by canal shares, and can lead to the appearance of unirrigated area.

6. Transfers of shares routinely occurs within a canal company in accordance with internal policies and procedures. These transfers can occur within a season from one season to the next. This is another reason why a snapshot in time may not provide an accurate picture of irrigated acreage.

7. The company's obligation is to be prepared to deliver water under all outstanding shares, regardless of the status of the underlying land. The company has no way of knowing whether land covered by shares will or will not be irrigated and must prepare to meet the share delivery obligation.

In addition to the factors above, one technical factor also causes potential errors in the 2017 irrigation delineation. Registration differences between the public land survey system lines and the aerial photo can result in different delineations particularly at the edges of fields where roadways exist. For example, Figure 3 shows a snippet of area near Filer. The aerial photos used for the 2013 and 2017 delineations are rectified differently against the section lines. This resulted in roadway areas being removed in the 2017 delineation, but the 2013 roadways areas were not added back in. The results in a double-counting of non-irrigated road areas.

Given the factors described above, together with the uncertainty in calculated irrigated acreage from aerial photo snapshots, the acreage used in the Fifth Methodology is reasonable and there is no clear and convincing evidence at this time to adopt a different figure.

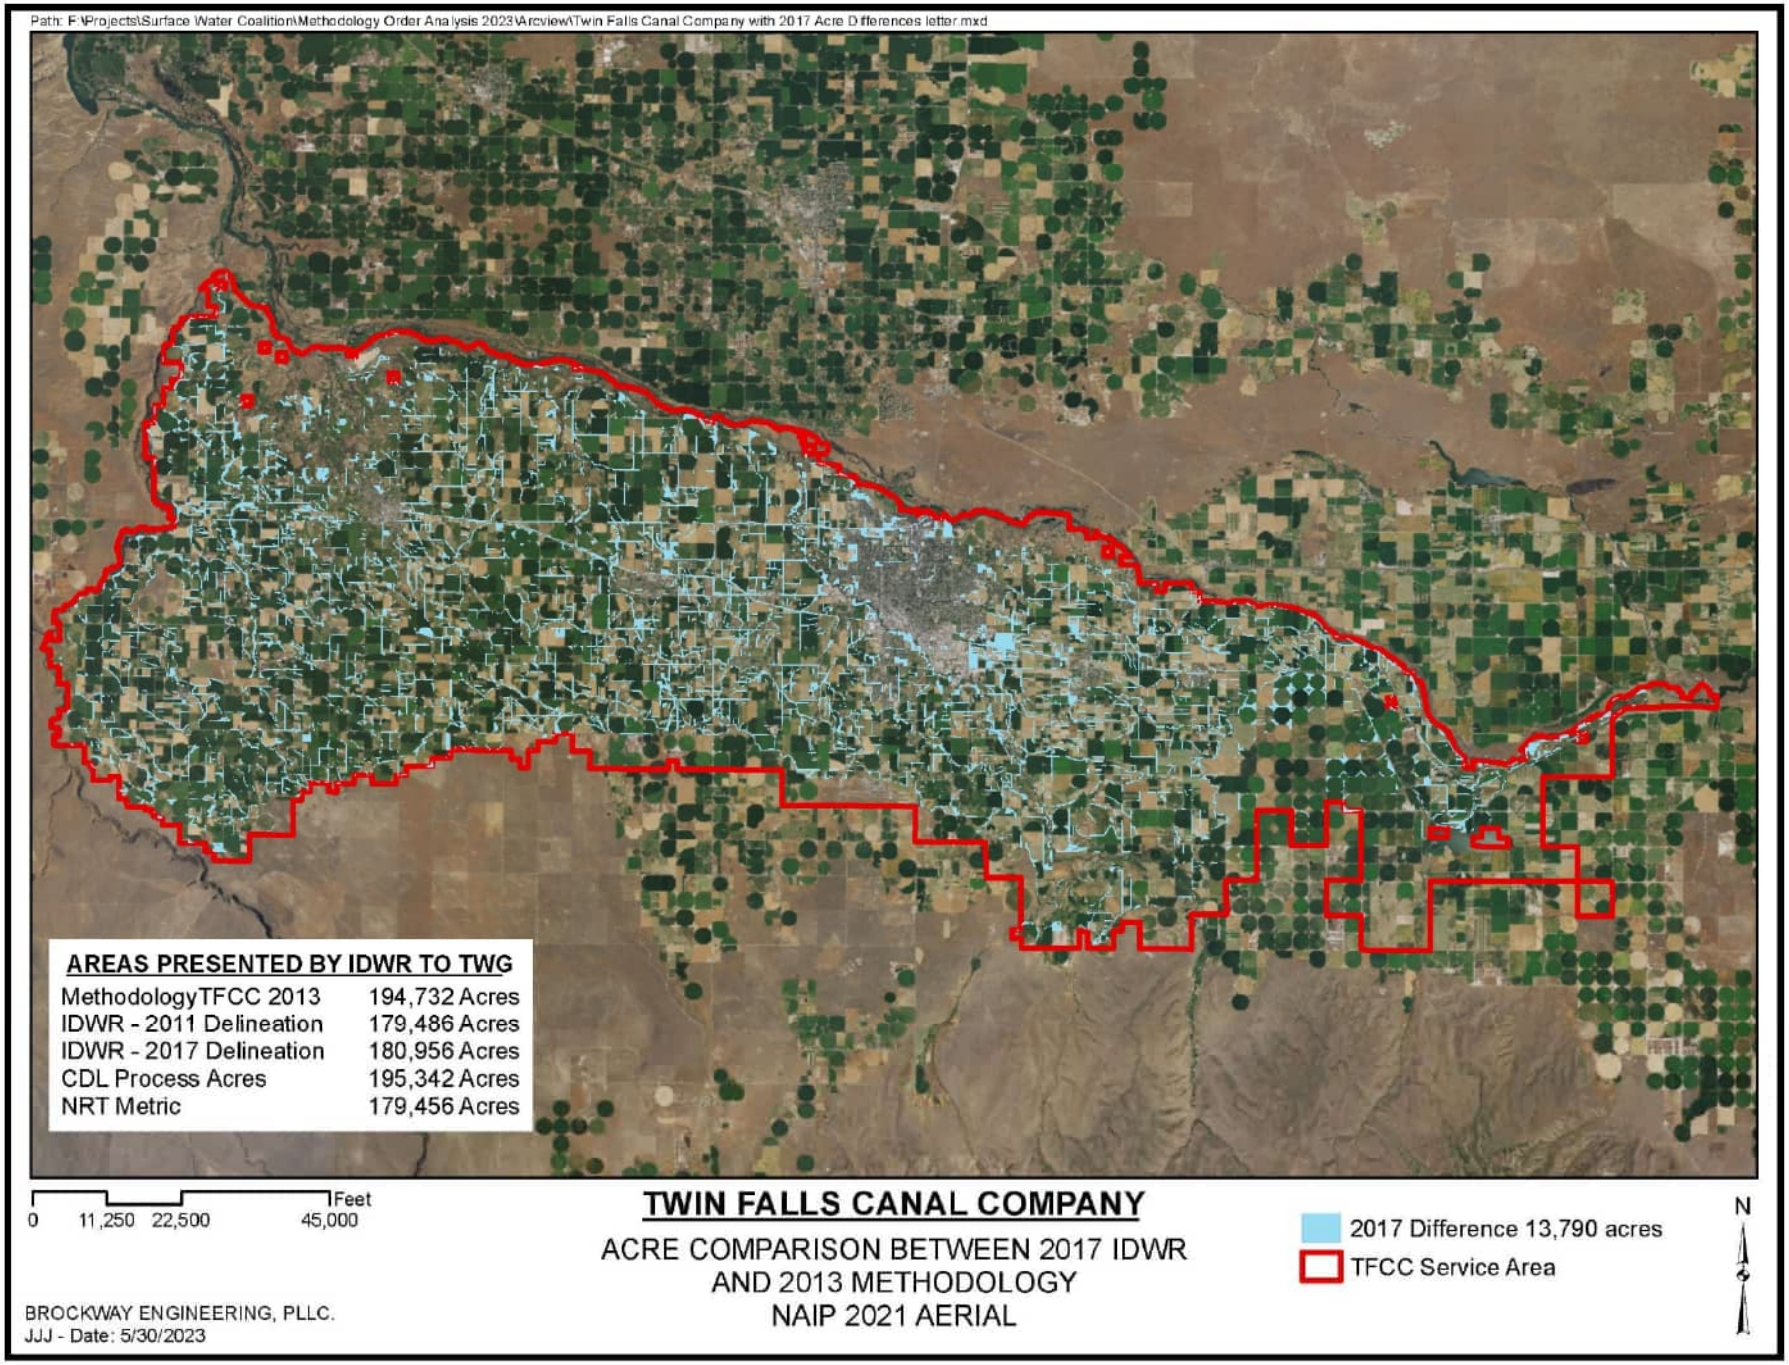

Figure 1. Map showing difference between IDWR's 2017 irrigated acreage delineation and the acreage used in the Methodology.

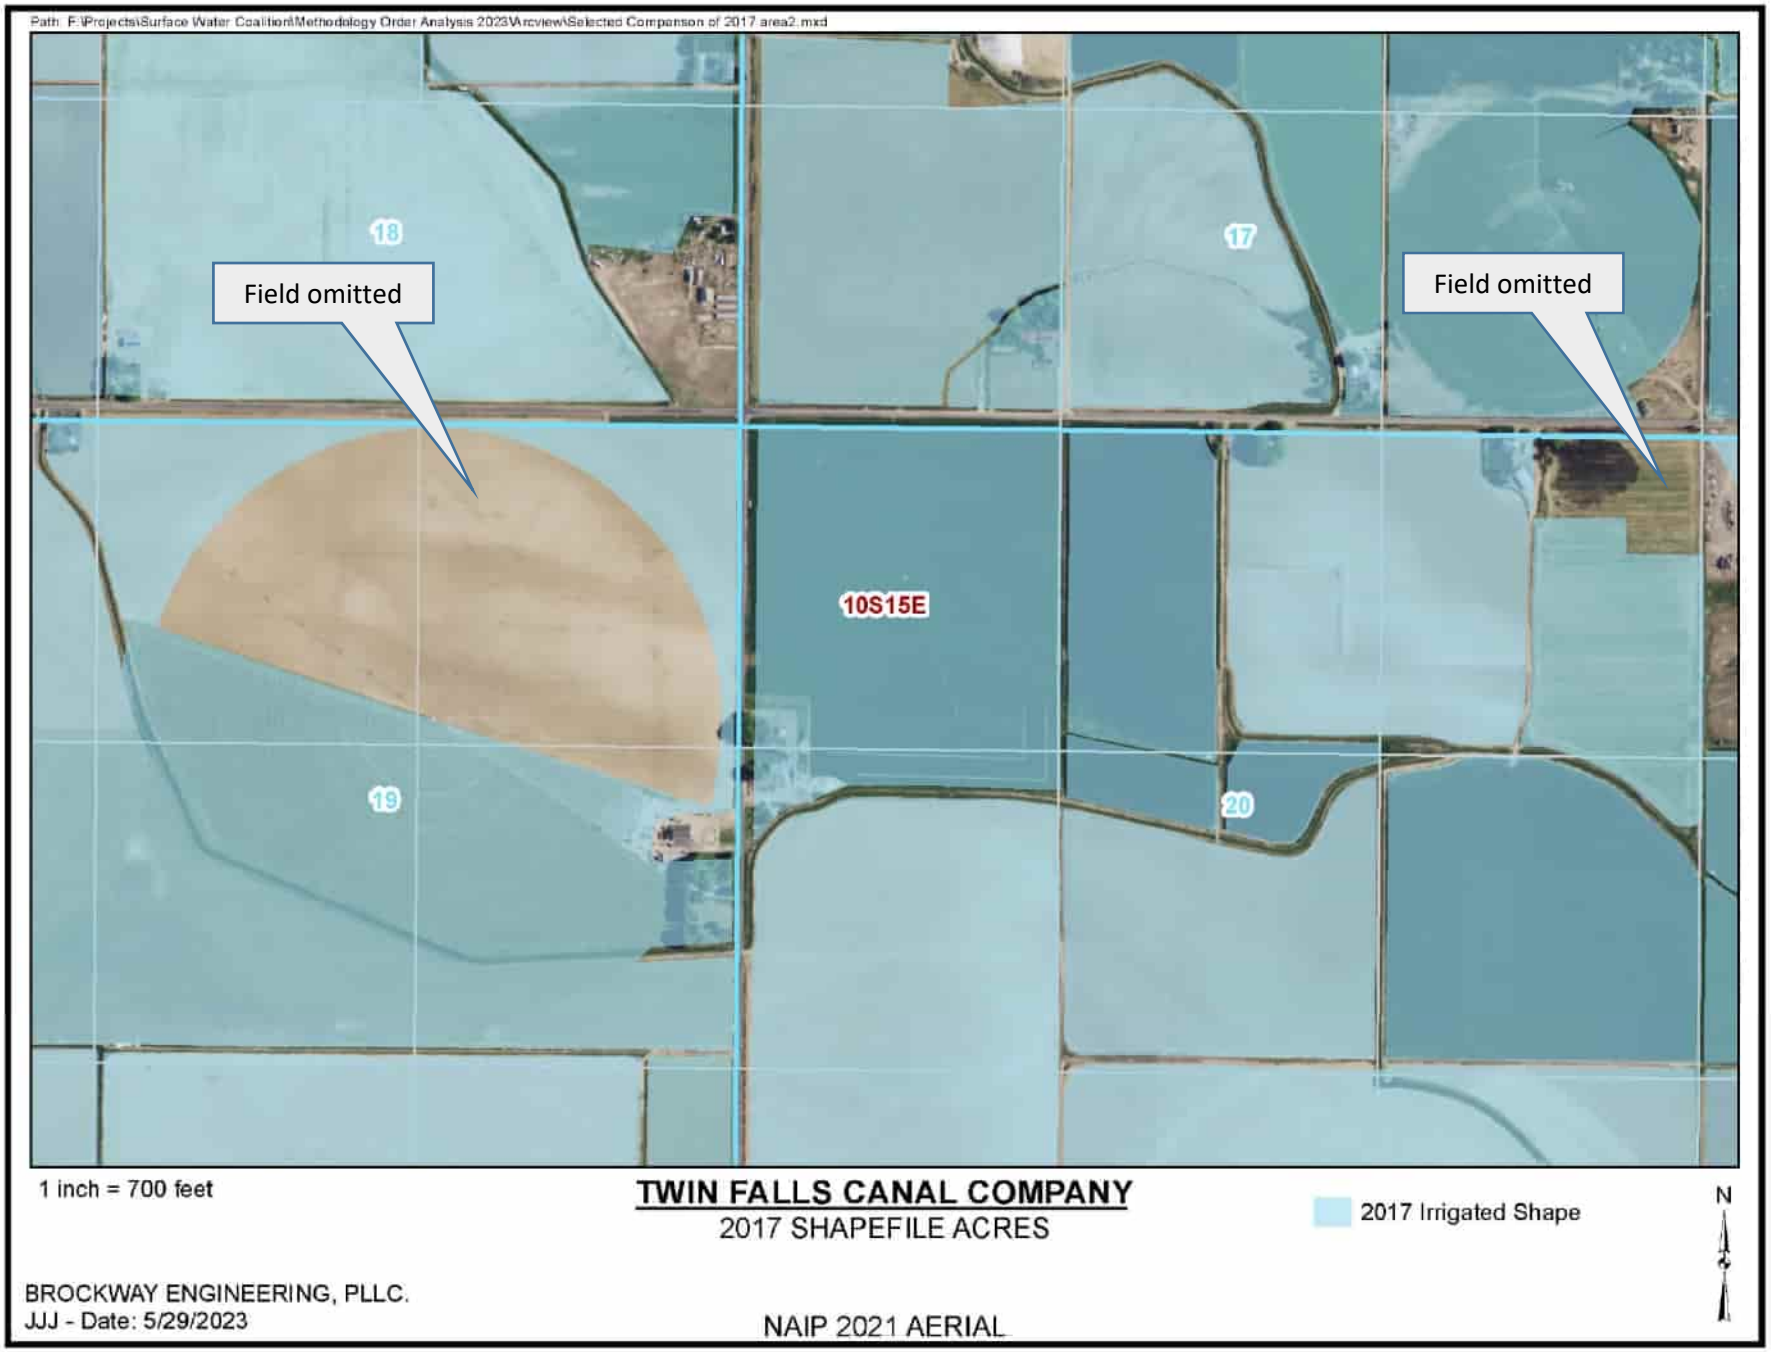

Figure 2. Example of irrigated fields omitted in IDWR's 2017 irrigated lands shape file.

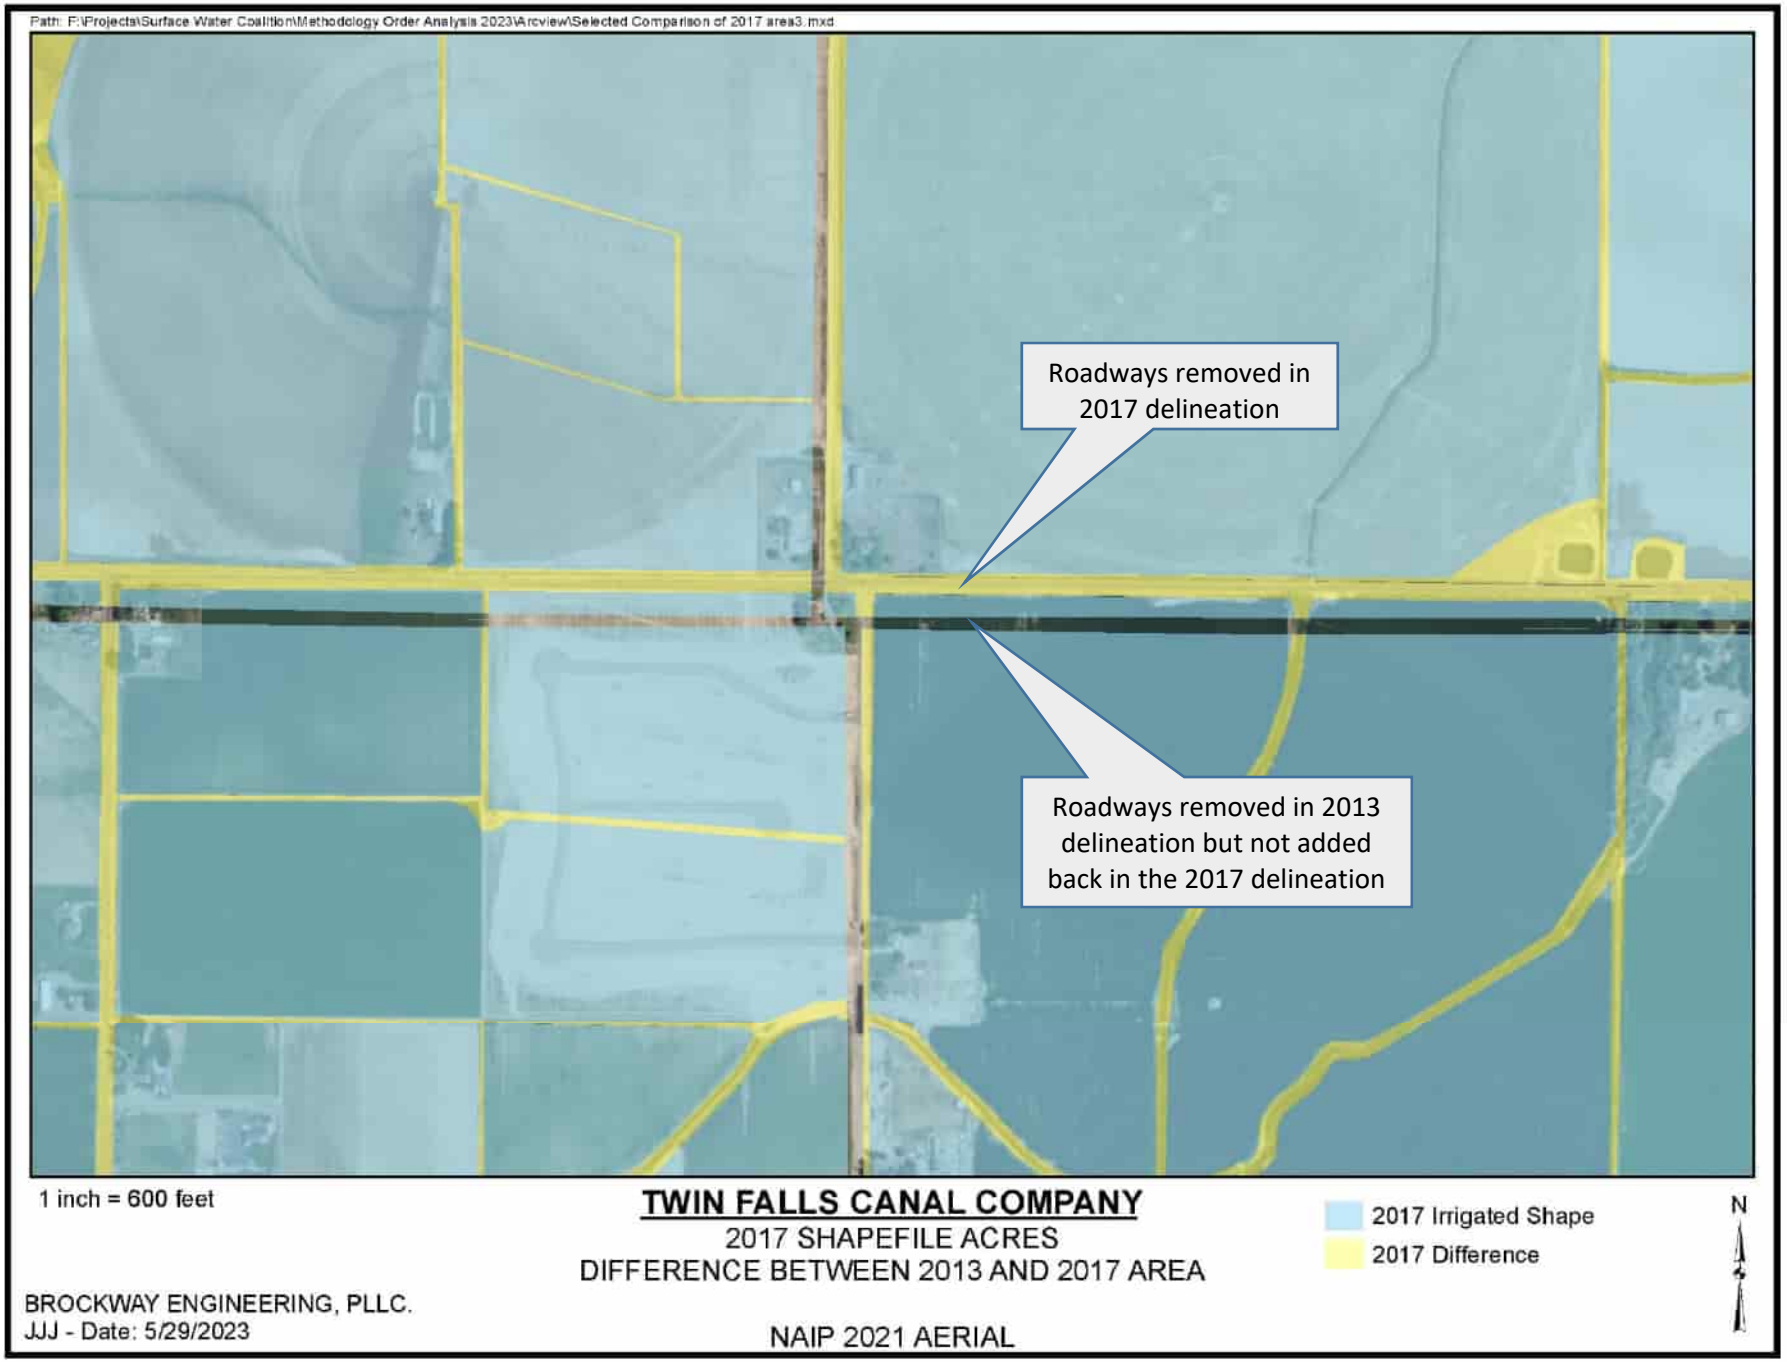

Figure 3. Example of PLSS registration difference that results in over-counting of acreage removed.

B. Trend in Twin Falls Canal Company Diversions

There have been statements alleging that the Twin Falls Canal Company (TFCC) diversions have been increasing over time. In order to evaluate these statements, the TFCC annual diversion data was analyzed for trends using a Mann-Kendall analysis. The Mann-Kendall test is a nonparametric statistical method to identify the presence of a significant trend in data over time.

TFCC diversion data were downloaded from Water District 1 (2023) to obtain diversion volume from 1977 through 2022. IDWR has produced adjusted diversion volumes accounting for wheeled or recharge water for the years 2000 through 2021. When wheeled or recharge water volume existed during specific year, those volumes were subtracted from the annual TFCC diversion volumes. The annual Water District 1 volumes, IDWR adjustments, and adjusted annual TFCC volumes are presented in Table 1 and plotted in Figure 4.

Table 1. Annual TFCC Diversion Volumes (ac-ft) from 1977 through 2022, IDWR wheeled or recharge water volumes, and adjusted TFCC annual volumes.

Year	WD1 Volume (acft)	IDWR Adjustments (acft)	Adjusted Volume (acft)	Year	WD1 Volume (acft)	IDWR Adjustments (acft)	Adjusted Volume (acft)
1977	1,023,025	0	1,023,025	2000	1,160,453	0	1,160,453
1978	1,024,890	0	1,024,890	2001	1,012,202	0	1,012,202
1979	1,094,456	0	1,094,456	2002	1,009,091	0	1,009,091

1992	978,113	0	978,113	2015	1,135,261	32,849	1,102,412
1993	1,056,573	0	1,056,573	2016	1,052,908	7,341	1,045,567
1994	1,060,839	0	1,060,839	2017	1,055,504	1,776	1,053,728
1995	1,076,070	0	1,076,070	2018	1,129,733	2,560	1,127,173
1996	1,162,930	0	1,162,930	2019	1,080,033	4,060	1,075,973
1997	1,108,898	0	1,108,898	2020	1,209,490	3,104	1,206,386
1998	1,026,848	0	1,026,848	2021	1,091,457	6,867	1,084,590
1999	1,099,775	0	1,099,775	2022	956,921	0	956,921

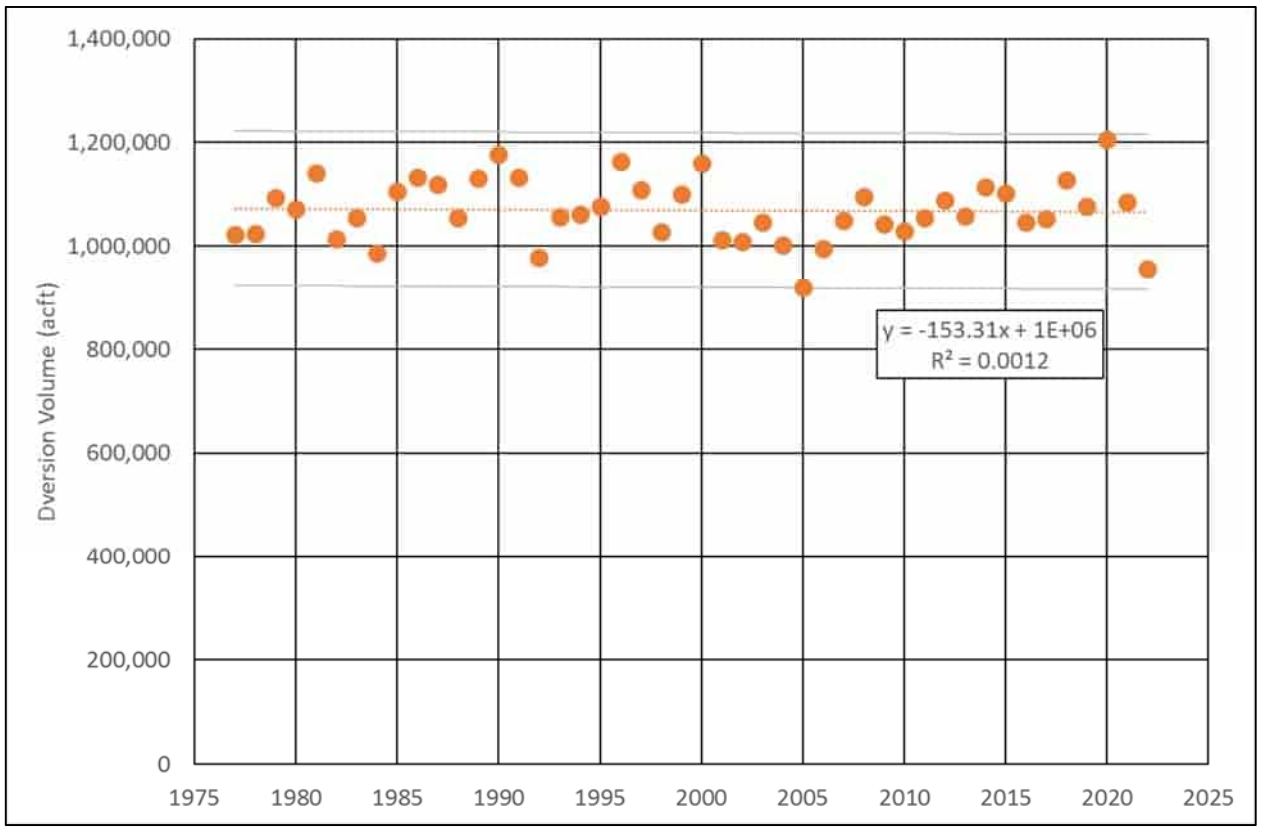

Figure 4. Adjusted annual TFCC diversion data from 1977 through 2022, presented in Table 1.

Figure 4 also includes a linear regression line through the data set, which is relatively level, but does have a slight downward slope. The R-squared value is 0.0012, which indicates that the linear regression equation is a poor estimator of the annual data points. However, all annual diversion data are within plus or minus 150,000 ac-ft of the estimated line, as shown in Figure 4.

Adjusted annual delivery data in Table 1 were subjected to the Mann-Kendall analysis to determine if there is a statistically significant trend in the diversion data. Based on the 46 years of data, the Mann-Kendall resulted with a Mann-Kendall T of -0.0126 and a p-value of 0.90954 (p-values of less than 0.05 are considered to have a significant trend), indicating that there is no statistically significant trend in the data set, and if any trend exists, it is a very weak downward trend. TFCC diversion data does not support the statements that the TFCC diversion are increasing over time.

C. SWC Crop Water Needs

Crop water needs (CWN) are a fundamental element in the determination of irrigation demand and irrigation project efficiency, E_p. Crop water needs are a function of weather conditions, i.e., temperature and precipitation, and crop mix since different irrigated crops require differing amounts of irrigation water at differing times of the year to meet the Et requirement of the individual crop.

IDWR has used the AgriMet stations at Twin Falls Kimberly and Rupert to determine temperature, precipitation and Et although there were discussions during the recent TWG meetings of changing to near real time (NRT) METRIC and PRISM to determine Et and precipitation. IDWR concluded they were not yet ready to change from the current use of the data from the AgriMet stations.

Determining the crop mix for the various SWC members has changed over the years as new data and data collection methods have become available. Prior to 2007, crop mix was based on NASS data reported on a county wide basis. Some, probably most, of these data were self-reported by growers with little verification by NASS. IDWR then prepared crop mix estimates for each SWC member by averaging the crop mix from the counties within which a SWC member's service area was located. The process of averaging the percentage of crop mix from the various counties has occurred since the methodology order was first implemented. The current DS RISD Calculator_2022 (Calculator) contains the crop mix averages for the period 2000 through 2014 as the basis for determining SWC member crop mix for that period.

As the Calculator currently exists, the CWN for the period 2000 – 2014 are based on the average crop mix for that period and the percentages of crop acreage that have changed in the mix over time are now lost in the calculation of crop water need on an annual basis. In other words, E_p is based on the adjusted irrigation demand for a given year in the 2000 - 2014 period, compared to the average crop mix for that period.

These conditions make any E_p trend analysis for the period 2000 – 2014 of little value because the crop mix to determine the CWN for any year has been lost in the Calculator.

Also during this period, the acreage used for TFCC was 183,589, for BID was 44,715 and for MID was 70,144 acres. The acreages for all 3 entities were increased beginning in 2015.

Since 2015 the CWN for a given year is based on the prior 3-year rolling average of the crop mix reported by the cropland data layers (CDLs) from NASS. The 3-year rolling average may have been implemented since the CDL data are not available until after the fact and the 3-year average is a method of estimating the crop mix for the current year to estimate the current CWN. The SWC list of issues urged the CWN need for each year be recalculated when the CDL data for that year become available, that way the CWN for each year used in the long-term average will be based on the crop mix for the year and not be based on the average crop mix of the 3 prior years.

An example of how the 3-year rolling average does not represent the following year Et, let alone the crop mix, is shown in Figure 5 below.

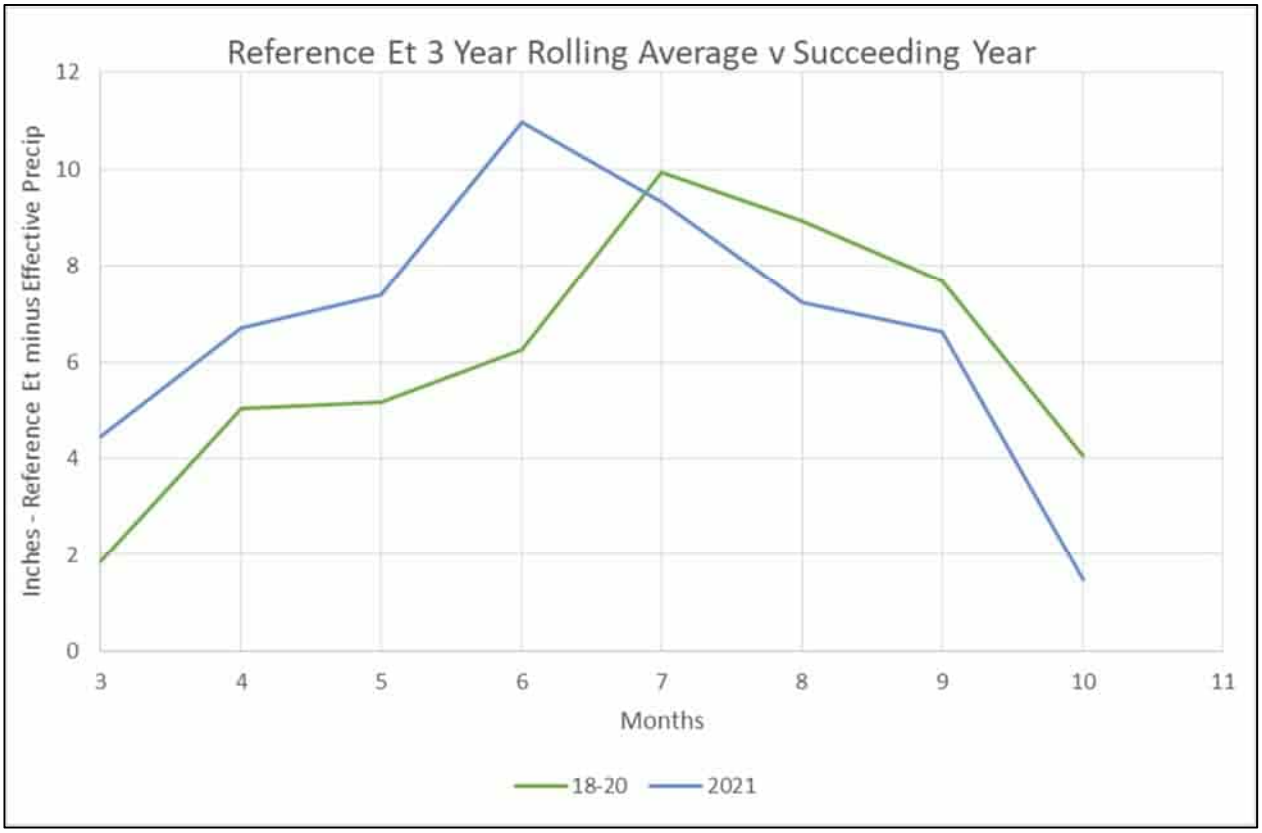

Figure 5. Reference ET 3-year rolling average vs. succeeding year.

Figure 5 shows the disconnect between the 3-year average currently used by IDWR to estimate the CWN for the following year and then not updating the efficiency calculations with the crop mix from the CDL data when those data become available. In this case, the calculated efficiency for the first part of the irrigation season will be artificially low since the actual water need will be over 1/3 higher during that part of the year than the Methodology indicates is required.

The recommendation to base the current year projected E_p on a 15-year rolling average seemed reasonable because that period covers the time when CDL data are available beginning in 2007. However, the 2007 – 2014 E_p calculations are not based on that 8-year period, but rather on the 2000 – 2014 period including years before CDL data became available and crop mix determinations were based on county averages.

As illustrated by the example above, if the 15-year rolling average is going to be implemented, the E_p needs to be recalculated for those 15 years so actual efficiencies are used instead of the rolling average.

C.1. Efficiency Trends Calculated with Existing Data Are Not Reliable

The ground water users are making the argument the efficiency trends since 2016 don't show efficient use of the available water supply or diligent management by the SWC Managers. As illustrated above, attempting to trend E_p for the SWC is not reliable due to the current method of

calculating CWN. In Manager Barlogi's deposition we heard about the continual improvements being implemented by the Twin Falls Canal Co. (TFCC) and when CWN's are appropriately calculated we believe those improvements will show continued reasonable use of the water resource.

The ground water users also complain the shoulder season (April and May, September and October) efficiencies vary unpredictably. The method of determining CWN affects the efficiencies during all times of the year, but the shoulder season efficiencies will always be more impacted by changing weather conditions than other times of the year. As Manager Barlogi testified it takes 3 days for changes in diversion rate by TFCC to reach the end of their system. TFCC has constructed a reregulation reservoir near the end of their delivery system to aid in making delivery adjustments at the end of their delivery system but changes in weather conditions, particularly precipitation, often lasts less than 3 days and trying to make diversion adjustments for precipitation occurring near the end of the delivery system isn't practical. Manager Barlogi also testified the TFCC system is large enough that weather conditions at one end of their system can be entirely different than at the other end of their system. Those conditions raise concerns about relying solely on the Twin Falls AgriMet station at Kimberly to adequately represent conditions throughout the TFCC service area as well as conditions throughout the North Side Canal Company, American Falls Reservoir District #2 and Milner Irrigation District service areas. In Matt Anders continued deposition on May 26 he testified about not having adequate staff resources to switch from using AgriMet stations for determining crop water needs to using NRT METRIC and PRISM to make those determinations. Perhaps those improvements can be implemented in the future.

As to the ground water user's recommendation to use a seasonal average efficiency to determine reasonable water use, the recommendation would not benefit either the water users or administrators. Neither would know if the water use was meeting standards until the season is over. Using monthly efficiencies allows both the water users and administrators to track the water use monthly and not need to wait until the end of the season to determine if the water use was reasonable.

C.2. Changes in Cropping Patterns Since the SWC 2007 Report

In Manager Barlogi's deposition he testified about the changes in cropping patterns since the number of dairies have increased in the Magic Valley. He mentioned particularly the increase in the number of acres of alfalfa hay and corn as well as the introduction of some double cropping acres with small grains or Triticale followed by corn in the same season[1]. Figure 6 below shows the change in alfalfa and corn acres since 2007 along with an increase in diversions by TFCC to meet the demands of the more water intensive crops.

[1] In IDWR's conversion of CDL crop types to AgriMet crop types on the Crop Water Need tab, IDWR considers only the small grain portion of the CWN and appears to omit the CWN for the corn crop that is grown in the same season.

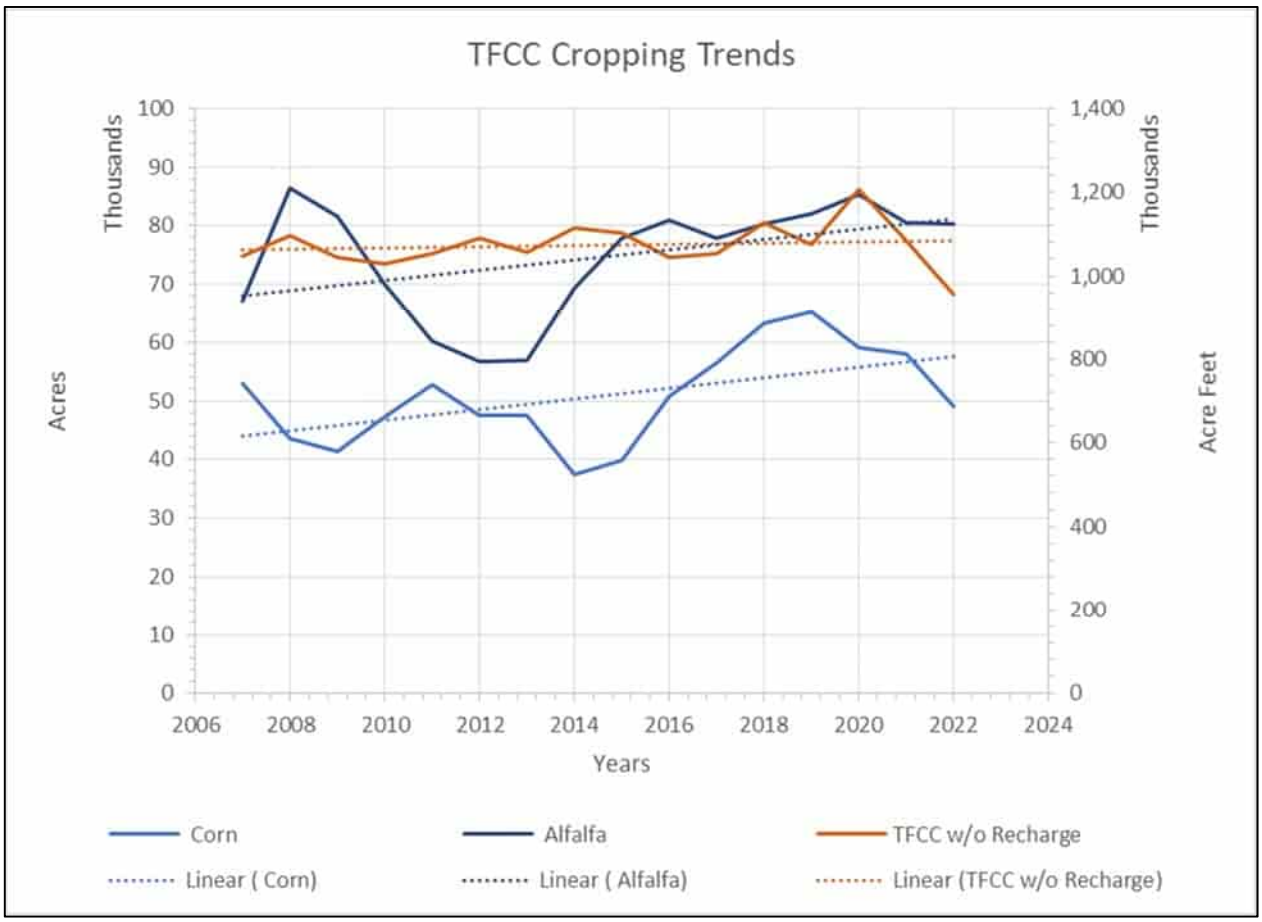

Figure 6. TFCC cropping trends.

This analysis was only completed for TFCC due to time constraints, but similar changes likely have occurred in the crop mix in other SWC member service areas.

Surface water delivery changes have also occurred in A&B Irrigation District with the delivery of surface water to acres in the Unit B portion of the project. Exhibit 1 attached shows the amount of surface water delivered to Unit B lands beginning in 2016. These diversions are included in the WD01 surface water delivery quantities and should be deducted from the total diversions when calculating the project efficiencies for the A&B water deliveries.

D. Factors Affecting Project Efficiency

Project efficiency (E_p) is defined as crop water need (CWN) divided by adjusted diversion. The Fifth Methodology Order uses an average monthly E_p based on a rolling average of the previous 15 years (see above discussion on calculation inconsistencies in the RISD spreadsheet). The project efficiency is a lumped parameter that accounts for all operational water requirements that are necessary for the project operation but do not directly go toward meeting the evapotranspirative demand of the crops.

Factors affecting project efficiency, i.e. factors that require diverting more than CWN, include the following

1. On-farm efficiency may range from 50% for gravity methods to 85% for a high-efficiency center pivot system.

2. Canal seepage varies from project to project, but can typically range from 20% to 30% of total diversion. Canal seepage is generally greatest during the initial startup of the project, when canal beds are dry.

3. Operational spill is always necessary in order to deliver water to users within the systems. Spill must be maintained in order to account for variations in demands by irrigators. Without spill it would be impossible to reliably serve the tail ends of the system.

4. Changes in meteorological conditions will affect on-farm demand, but the overall project diversion cannot respond to short-term demand changes. For example, the onset of a cool, rainy period could lead to rapid decreases in on-farm demand, but if the project diversion were to be reduced, delivery shortages would likely occur when the ordinary warm weather returned, and these shortages would be concentrated toward the lower end of the project. Only if the cool period were sustained for many days could the project diversions potentially be adjusted.

5. Conversion to sprinkler methods from gravity methods always leads to an increase in on-farm efficiency, but may actually lead to a decrease in overall efficiency in a large system for the following reasons:

    1) the on-off nature of sprinkler pumping leads to more variation in demand and a greater need for operational spill;

    2) reduction in incidental recharge from irrigation leads to reduction in drain flows that are relied upon for re-delivery. With gravity irrigation methods, subsurface storage occurs, drain flows are sustained, and the drain water is treated as project water that can be reused by downstream irrigators later in time. Lower drain flow necessitates greater total diversion from the river and greater flows within laterals to serve lands that may have been previously served primarily by drain flows. A similar effect occurs when runoff is reduced by conversion of fields to sprinkler irrigation.

    For these reasons, it is not correct to assume that conversion to sprinkler methods will necessarily lead to an increase in overall project efficiency.

6. In the shoulders of the irrigation season, efficiencies are naturally low. When canals are turned on in April, it make take several days to "charge" the system by filling the volume within the canals and laterals and overcoming the high initial seepage rate. During this time, CWN is low, on-farm irrigation diversions are minimal, and overall project efficiency is therefore very low. Similarly, during October the CWN is low but water is still needed in the

canal system in order to convey water to the end of the system to meet tail-end delivery obligations. In addition, late-season water may be used by irrigators to increase soil moisture storage or for erosion mitigation rather than to meet CWN. The Fifth Methodology incorporates provisions to ensure that the RISD is not underestimated in April, nor under- or over-estimated in October.

SWC projects have been implementing a number of measures to better manage water within their projects. Specifically, within the last 10 years the Twin Falls Canal Company has implemented

- Flow measurement with telemetry
- Automated lateral gates
- Regulating storage (Kenyon Pond)
- Canal lining
- Reduction in operational spill to minimum necessary

In summary, when a system is comprised of thousands of farms and all of the operational water requirements within the project are considered, overall project efficiency is much lower than on-farm efficiency and a value of 35% to 50% is typical and reasonable. A simple example calculation demonstrates this: assuming that the average on-farm efficiency is 65% (half gravity at 50% efficiency and half sprinkler at 80% efficiency), canal loss is 20% of the diversion, and required operational spill to run the system is 15% of the diversion, the overall project efficiency would be 42%. This does not account for other harder to quantify factors such as seasonal shoulder effects and weather changes reducing CWN or providing effective precipitation.

Changing from an 8-year average to a 15-year average project efficiency is justified based on reduction of variability. If a project efficiency estimate can be assumed to be approximately normally distributed, the standard deviation of the estimate is proportional to $1/\sqrt{n}$, where n is the number of years in the period of record. Moving from an 8-year to a 15-year average would reduce the standard deviation of the estimate by 27%.

F. Effect of Irrigated Area Reduction on RISD

It has been asserted that if the irrigated area within the TFCC service area is actually 180,956 acres instead of 194,732 acres, the RISD would be reduced proportionally by 86,600 acre-feet and thus the in-season demand shortfall would be eliminated. The 86,600 acre-feet figure was calculated by multiplying the difference in acres (13,776) by the crop irrigation requirement of 2.2 ac-ft/acre, and dividing by the average monthly project efficiency of 0.35 (G. Sullivan declaration, May 7, 2023).

This assertion does not account for the fact that in the Methodology, the monthly project efficiencies are calculated as crop water need for the full 194,732 acres (for the 2015-2021 period) divided by the observed diversions, and then RISD for the current season is based on 1) the baseline year observed diversion demand and 2) in-season adjustments based on monthly

crop water need and project efficiency. If the acreage were in fact less than 194,732, the calculated project efficiency would also be lower. In other words, it is not valid to divide the crop irrigation requirement by 0.35, because 0.35 is not the correct number if the acreage were in fact lower than 194,732. A reduction in RISD would only be valid if project efficiency is independent of acreage, but in fact efficiency is directly dependent on acreage. Further, it has been demonstrated herein that the project efficiency is reasonable.

G. Supplemental Groundwater Usage

Usage of private groundwater wells for supplemental purposes on surface water irrigated lands occurs within the Twin Falls Canal Company service area, but the percentage of water supply provided by groundwater is generally low due to the overall reliability of the surface water shares.

Groundwater supply systems on a particular farm are rarely standalone systems, but are hydraulically interconnected with the surface water supply systems. Typical configurations involve multiple fields, pumps, and application systems that are interconnected and used in a complicated fashion. The only way to accurately assess the degree of groundwater usage and equivalent acreage irrigated by groundwater would be to ground-truth each individual system with the farm operator. Insufficient data exists to make this determination.

The usage of groundwater, even if it could be quantified, would likely not change the total irrigated acreage since groundwater is generally used as a supplemental supply to land already covered by canal shares and it is required to use surface water as the primary supply.

Furthermore, even if groundwater-supplied acreage could be quantified, it would have the effect of slightly lowering the calculated project efficiencies, because the same surface water diversion volumes would be applied to fewer acres. These lower efficiencies would then be utilized in the methodology for determining RISD.

H. Baseline Year Discussion

In order to quantify the initial surface water demand in the Methodology Order, IDWR identifies a Baseline Year (BLY). The order requires that the BLY have the following characteristics: (1) above average surface water coalition diversion volume, (2) above average temperature, (3) above average evapotranspiration (ET), (4) below average precipitation, and (5) not be a year of limited supply. The data and criteria were presented to the TWG in November 2022 by Matt Anders, and the summary table is replicated below in Table 2 (Anders, 2022). Furthermore, detailed explanation of each criteria, including graphs of the data, are included in the Fifth Methodology Order.

Table 2. BLY Selection Criteria presented by M. Anders on November 11, 2022 to the TWG. Only two years met all of the evaluation criteria, which were 2018 and 2020 (highlighted in yellow).

	(1)	(2)	(3)	(4)	(5)	
Year	Above Average SWC Diversions (2000-2001)	Above Average GDD (1992-2021)	Above Average ET (1991-2021)	Below Average Precipitation (1992-2021)	Above Average Heise Runoff (1992-2021)	Supply Not Limited (Above Average) (1992-2021)
2000	X	X		X		
2001		X	X	X		
2002			X	X		
2003		X	X			
2004				X		
2005						
2006		X	X		X	X
2007	X	X	X	X		
2008	X		X	X	X	X
2009	X				X	X
2010				X		
2011				X	X	X
2012	X	X	X	X		
2013	X	X	X	X		
2014	X	X			X	X
2015	X	X		X		
2016		X				
2017		X		X	X	X
2018	X	X	X	X	X	X
2019	X				X	X
2020	X	X	X	X	X	X
2021	X	X	X	X		

IGWA argued that IDWR should consider the rank within the period of record when updating the BLY, stating that it should be similar to the previous BLY (Sigstedt, 2023). However, the rank of diversion volume of BLY is not one of the criterion to be used by IDWR in establishing a BLY. The previous BLY was an average of years 2006, 2008, and 2012, and IGWA reported the diversion volume rank of about the 55-th percentile for the period of record 2000-2015 (Sigstedt, 2023). IGWA further argues that the 2018 diversion volume of 3.381 maf is at the 90-th percentile and is therefore too high.

In the Fifth methodology order, IDWR states, "Equality in sharing the risk will not adequately protect the senior priority surface water right holder from injury. Actual demand shortfalls to a senior surface water right holder resulting from predictions at the start of the irrigation season based on average data unreasonably shifts the risk of shortage to the senior surface water right holder. Therefore, a BLY should represent a year(s) of above average diversions and should not represents year(s) of average or below average diversions." (emphasis added)

The percentiles provided by IGWA appear to be derived from a ranking analysis of available data. To illustrate the percentiles in more accurate detail, a normal distribution was fit to the annual diversion data and percentiles estimated from the distribution (a normal distribution

appears to be a good choice in this case; a lognormal assumption yields almost identical percentiles). Statistics calculated in this way from the 2000-2021 dataset are shown in Table 4.

Table 4. Statistics of total annual SWC diversion calculated from a normal distribution fit.

Statistic	Value (MAF)
Mean	3.201
+1 s.d.	3.380
+2 s.d.	3.559
50-th	3.201
75-th	3.322
80-th	3.387
90-th	3.430
95-th	3.495
99-th	3.617

In order to protect the senior water right holders, the diversion volume of a BLY should be above average, not average or close to average. IDWR has determined that years with an average diversion will not be protective of the senior water right holders. IGWA proposes a BLY with a diversion volume of 3.225, just above average at the 55th percentile (Table 4). The volume at one standard deviation from the mean (84th percentile) is 3.380 maf, essentially the same volume as 2018. A more conservative approach would be two standard deviations from the mean or 3.559 maf, which would be in-line with standard engineering practices when a very high level of certainty is desired. Still, using 2018 as the BLY provides a reasonable factor of safety without being extreme, and we concur with this selection.

One potential approach that could be evaluated is identifying a BLY for each SWC entity, because a universal BLY selection does not likely take into account all of the variables that may influence the diversion volume for particular entities. This approach would result in a potentially different BLY based on the closest year to 1 standard deviation from the mean for each SWC entity, as follows: A&B = 2018, AFRD2 = 2014, BID = 2018, Milner = 2017, Minidoka = 2007, NSCC = 2020, and TFCC = 2018. The total diversion volume of these years sums to 3.41 maf.

I. Conclusions

- Twin Falls Canal Company surface water diversions show no statistically-significant trend.
- Applying a reasonableness test of project efficiencies based on operational water requirements and constraints within large canal project demonstrates that efficiencies calculated in the Fifth Methodology area reasonable.

- It is not unreasonable to see flat or declining project efficiencies even though sprinkler conversions are continuing to occur.

- Changing from an 8-year to a 15-year rolling average is justifiable based on statistical considerations.

- The irrigated acreage used for Twin Falls Canal Company in the Fifth Methodology Order is reasonable.

- In the Fifth Methodology calculation procedures, use of a lower irrigated acreage for Twin Falls Canal Company would not change the in-season demand shortfall, because even though a lower acreage would result in lower crop water need, it would also result in a lower project efficiency and the RISD would remain unchanged.

- Supplemental groundwater diversion or acreage cannot be accurately assessed with the available data.

- The diversion volume in the Fifth Methodology baseline year of 2018 is at the 84th percentile and provides a reasonable factor of safety to protect senior water right holders. If higher certainty is desired, the value at two standard deviations from the mean could be used.

- Annual project efficiencies, E_p, need to be recalculated with the CDL data for each year to better represent the actual E_p. Calculating actual E_p values will better address changes in cropping patterns over time.

Exhibit 1
A&B Irrigation District Unit B Deliveries

Conversion Water - Acre Feet Pumped to Unit B Lands

Year	Natural Flow	Storage	Groundwater	Total Pumped
2016	790.4	7812.9	21.8	8,625.1

EDUCATION

1992-1995	University of Iowa, Iowa City, Iowa Iowa Institute of Hydraulic Research Ph.D., Civil and Environmental Engineering Research was conducted under the Hunter Rouse Scholarship, leading to the doctorate granted in December 1995.
1989-1992	University of Idaho, Moscow, Idaho. B.S., Civil Engineering
1988-1989	Northwest Nazarene College, Nampa, Idaho. Major: Physics.

EXPERIENCE

Professional

Managing Member, Brockway Engineering, PLLC
August 1995 to present. Areas of particular expertise include:

- Hydraulic, hydrologic, and environmental evaluations
- Design of groundwater wells and irrigation systems
- Computer modeling of water resources systems
- Statistical analysis and stochastic modeling
- Design of hydraulic control structures and systems
- Rainfall-runoff and flood plain-floodway analysis
- Idaho and western states water right transactions
- Economic analysis of water resources systems

P.E. Registrations: Idaho, Wyoming, Nevada

Research

Graduate research: Quantitative assessment of the uncertainties associated with hydrologic reconstructions in augmenting historical information about low-flow phenomena.
Dr. A. Allen Bradley, Iowa Institute of Hydraulic Research, University of Iowa.

Undergraduate research: Leak detection in long oil pipelines under transient conditions
Dr. C. P. Liou, University of Idaho.

HONORS and AWARDS

University of Idaho Alumni Award for Excellence, 1992
Outstanding Senior Civil Engineering Student, 1992
Tau Beta Pi member
Phi Kappa Phi member
Golden Key National Honor Society member
National Dean's List member
Hunter Rouse Fellow, University of Iowa, 1992 - 1995

OTHER PUBLICATIONS

Dr. Brockway is the author or co-author of over 100 technical publications related to consulting services performed in the hydraulics, hydrology, and water resources fields. A listing can be provided upon request.

AREAS OF EXPERTISE AND PRACTICE

Computer Modeling

Development, testing, and implementation of computer models for deterministic and stochastic analysis of hydraulic and hydrologic systems, both surface water and groundwater.

Groundwater Evaluations

Data collection, evaluation, and analysis of groundwater flow systems and contaminant transport.

Hydraulic Analysis and Design

Design and analysis of canal diversion and regulation structures, water measurement structures, spillways, pipelines, culverts, aqueducts, canals, pumping stations, surge-control devices, groundwater wells, irrigation systems, pipeline networks, municipal distribution systems.

Land Application of Wastewater

Evaluation and design of all aspects of wastewater treatment by land application, including hydrogeologic analysis and modeling, parameter loading analysis, environmental impact evaluation, system management and design, and permit acquisition and compliance.

Stream Bank Protection

Analysis of sedimentation and meander pattern evolution in natural waterways, both mountainous and low-gradient. Design of bank stabilization and protection structures. Design of river management projects including flood channel restoration, natural gravel bar removal, drop structures, and sills.

Water Rights Evaluations

Hydrologic analysis and transaction preparation for water right permits and transfers in compliance with current state policies, rules, and statutes. Crop evapotranspiration determination, climatic analysis; statistical analysis of climate and crop use variables; water requirements evaluations for irrigation, domestic, commercial, and industrial applications; consumptive use determination; field investigations, measurement and analysis of diversion capacity and water requirements.

Flood Analysis and Control

Estimation of flood-frequency relationships in natural and man-made drainages using statistical and deterministic approaches. Hydraulic analysis and computer modeling of waterways to predict water surface elevations and extent of inundation during flood events. Design of flood control structures and bank protection structures.

Water Demand and Sufficiency Analyses

Analysis and determination of water supply suitability, source development feasibility, and other factors affecting water supplies for municipalities, residential developments, and industry.

Hydrography

Discharge measurements in open-channels and closed-conduits using current meters, in-pipe impeller and propeller meters, and non-intrusive ultrasonic meters.

Professional Experience

Project Engineer — 2006 – Present
Brockway Engineering, PLLC
Twin Falls, Idaho

Project Engineering on hydrologic and hydraulic engineering design, including: well design, well construction, well testing, water rights, water right transfers, pipeline design, water distribution systems, stream channel evaluation, floodplain assessment, irrigation water demand, and potable water demand.

P.E. Registrations: Idaho, Utah, and Oregon

Graduate Research Assistant — 2002 – 2006
Department of Food, Agricultural, and Biological Engineering
The Ohio State University, Columbus, Ohio

Research consisting of: 1) evaluation of channel forming discharges, 2) two-stage channel design procedures, 3) nutrient performance within two-stage agricultural channels, and 4) theoretical nutrient spiraling under restored riparian projects.

Areas of Expertise

Developed numerical groundwater flow simulations using FEMWATER and Groundwater Modeling System (GMS). Experience in groundwater modeling, flood plain evaluations, stream bank restoration and protection, surface water quality modeling, and water right transactions.

BACKGROUND

David is an engineer in the Denver-based natural resources consulting firm of ERO Resources Corporation (ERO). For over 25 years, David has managed ERO's Idaho office. He specializes in the identification, analysis, and resolution of water issues including coordination with other professionals in multidisciplinary projects. David has more than 45 years of experience and expertise in water resources and management, covering a broad spectrum of disciplines including surface and ground water supply and use studies, water right evaluations, water quality evaluation and monitoring, project management, alternative dispute resolution, litigation support and expert witness testimony, and technical input on legislative and administrative matters.

SUMMARY OF EXPERIENCE

Water Right Investigations
For 11 years, acted as project manager for IDWR's role in the SRBA. An understanding of water rights and management ability were essential for the successful development of the criteria and process for the identification and evaluation of 150,000 claims to water rights. David continues to assist clients with water right investigations including adjudication and administrative processing, evaluation and transfer, and the development of new rights and protection of senior rights.

Litigation Support and Alternative Dispute Resolution
Designated as an expert in water right adjudications by the SRBA court. Provides expert testimony before the court on all aspects of water right adjudications as well as hydrology and water right administration issues. Provides expert testimony and settlement support for storm water conflicts and right-of-way issues between water users and nonwater users.

Water Supply Evaluations, Development, and Permitting
Assists clients with the permitting and development of water uses. A water supply evaluation is required for most new water right filings and for many filings for changes. Delivery system designs are sometimes included with the development and supply evaluations.

Water Quality Evaluation, Monitoring, and Management
Experienced in designing and implementing water quality monitoring programs for various water users. This includes knowledge of state standards and Total Maximum Daily Load requirements, and how water users can help protect their water uses with water quality data.

Project Experience:
Water Right Investigations

Surface Water Coalition, ID
Provided analysis and recommendations for resolution of water delivery call by senior surface water users against junior ground water users. Analyzed historical water distribution practices for delivery of storage and natural flow water to preserve historical enjoyment of the water resource.

Snake River Basin Adjudication, ID
Developed criteria and procedures to investigate the existence and extent of tens of thousands of water rights.

Little Land and Livestock, Inc., ID
Evaluated water rights for a potential land purchase. Secured new water rights for development of additional land for irrigated agriculture. Provided technical analysis to resolve conflicts between potential new water use and existing water uses.

Modoc Point Irrigation District, OR
Determined the extent of water use for irrigation in support of water right claims in the Klamath River Adjudication.

Litigation Support and Alternative Dispute Resolution

Office of the Idaho Attorney General, ID
Designated by the SRBA court as an expert in water right adjudications. Provided mediation support for resolution of federal reserved water rights. Acted as hydrology expert for litigation of federal reserved water right claims.

Surface Water Coalition, ID
Provided mediation support and expert testimony in support of water delivery call by senior surface water users.

Settlers Irrigation District, ID
Provided mediation support and expert testimony to resolve conflict over irrigation district rights-of-way and encroachment from storm water discharge.

Middle Fork Lodge, ID
Provided expert testimony to establish right-of-way for water delivery prior to creation of a wilderness area and designation of the forest.

Shoshone-Bannock Reserved Water Right Negotiations, ID
Acted as co-chair of the state, Indian, federal, and private technical advisory committee.

Riddle Ranch, ID
Served as technical expert/negotiator for resolution of federal reserved water rights of the Duck Valley Indian Reservation.

Methow Valley Ditch Users Association, WA
Analyzed ground water/surface water interaction and supply.

Federal Instream Flow Coalition, ID
Provided mediation support for resolution of federal reserved water rights and Endangered Species Act water demands.

Idaho Office of the Attorney General, ID
Acted as hydrology expert for litigation of federal reserved water rights.

Water Supply Evaluations, Development, and Permitting

Idaho Office of the Attorney General, ID
Evaluated the surface water supply of a river drainage basin for equitable allocation among state law-based water right water users and federal reserved-based water right water users.

Surface Water Coalition, ID
Evaluated the impact of surface water supply by the diversion and use of ground water.

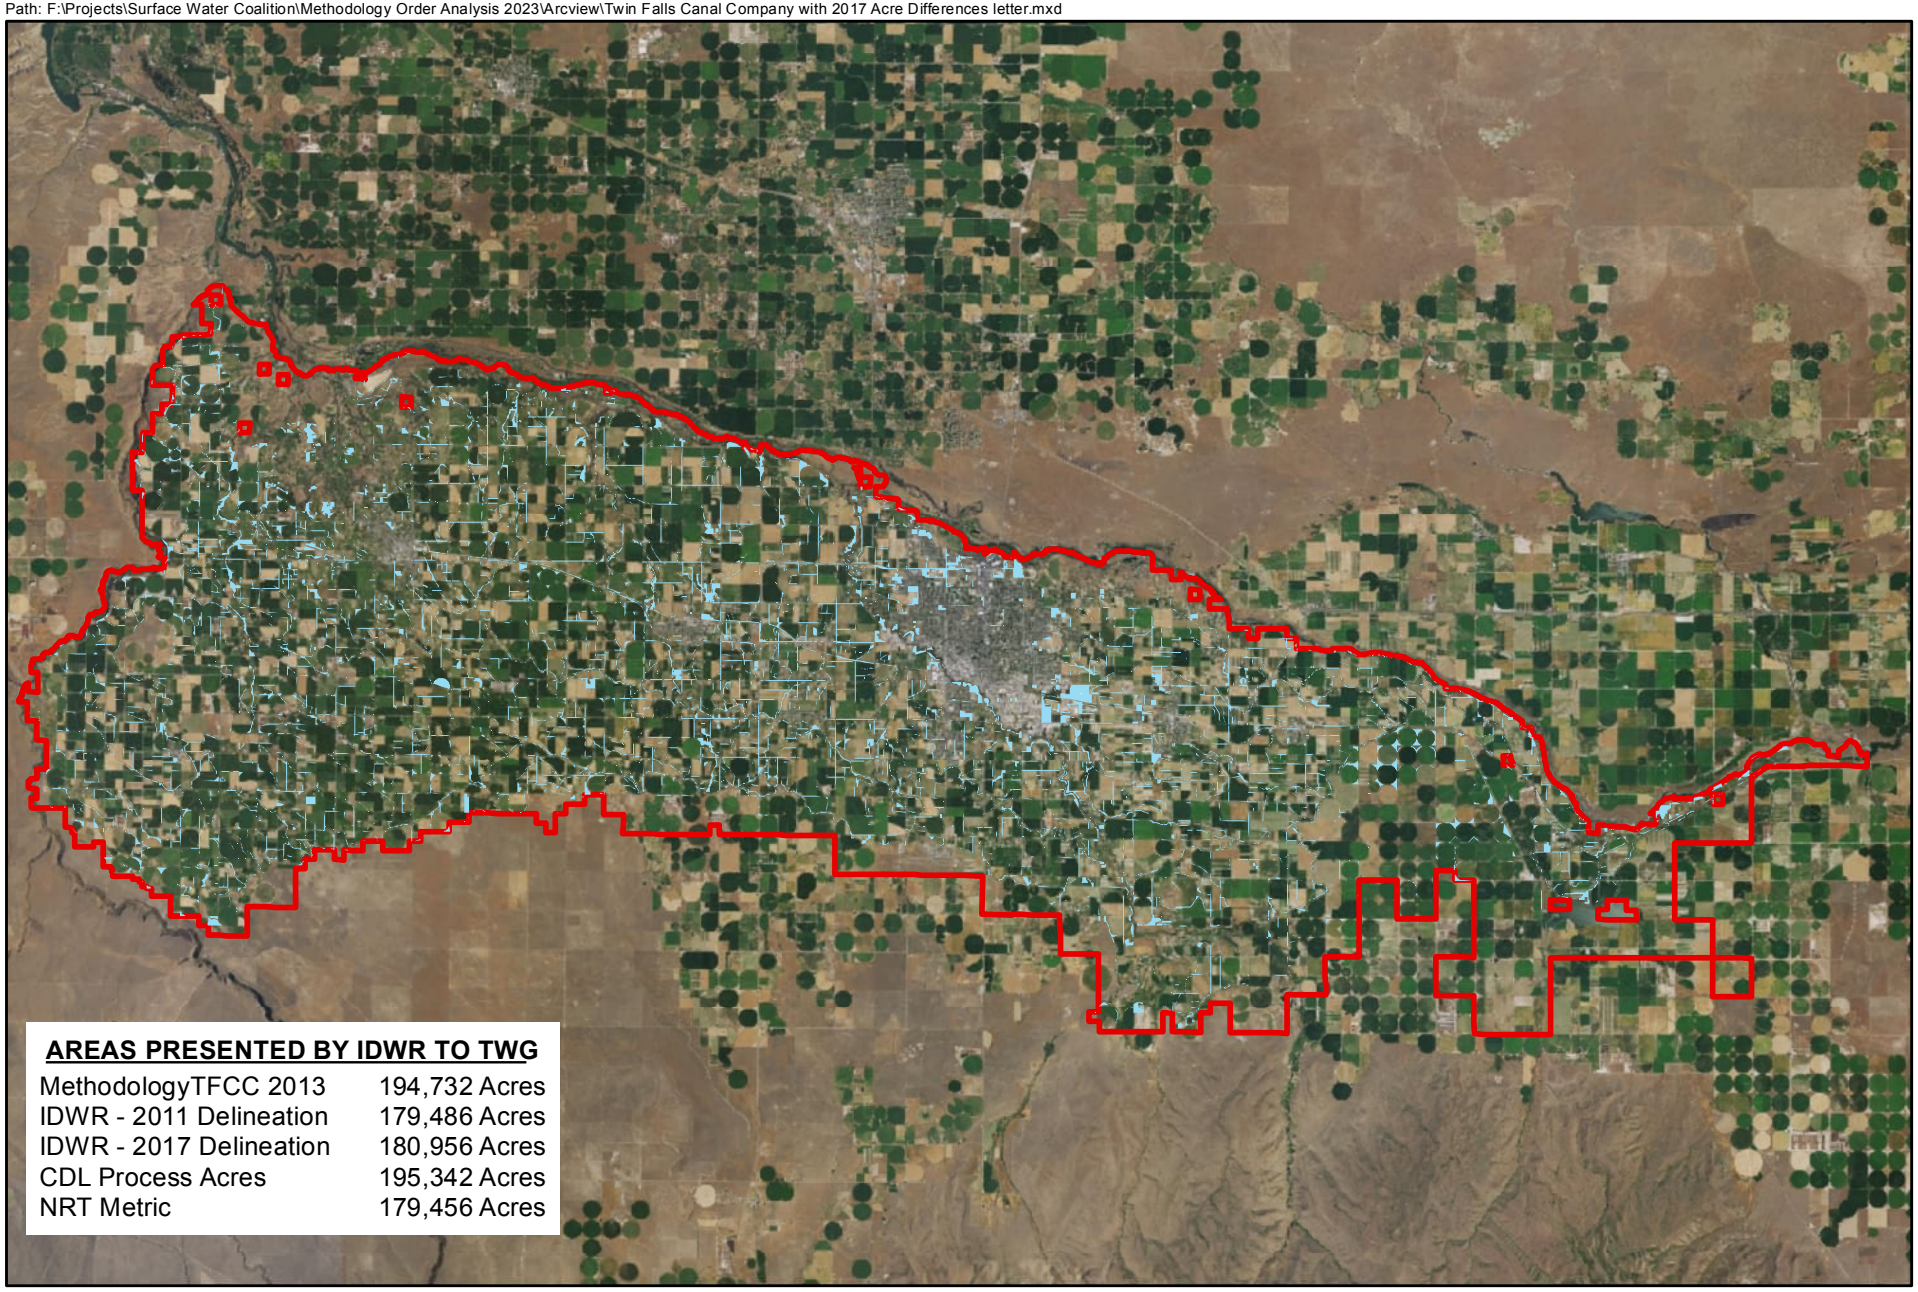
Idaho Power Co., ID
Evaluated the impact of the proposed development of the company's water supply for power generation.

Big Lost River Basin, ID
Provided expertise regarding the surface and ground water hydrology and the administration requirements for a ground water recharge project.

District Water Supply, Boise River, ID
Evaluated the impact of a proposed water right transfer on irrigation. Identified and quantified changes to ground and surface water supply if the transfer was approved.

City of Coeur d' Alene, ID
Prepared an application for consolidation of all city water rights to allow for full use of the water rights and development of a new well.

Federal Instream Flow Coalition, ID
Evaluated the hydrologic impact of the historical water development in southern Idaho on river flows for Endangered Species Act-listed salmonids.



Water Quality Evaluation, Monitoring, and Management

Pioneer Irrigation District, ID
Provided project design, implementation, and management for their water quality sampling program.

Wilder Irrigation District, ID
Provided project design, implementation, and management for their water quality sampling program.

Water Users in Owyhee County, ID
Provided project design, implementation, and management for their water quality sampling program.

C.L. "BUTCH" OTTER
Governor

GARY SPACKMAN
Director

MEMORANDUM

To: Gary Spackman, Director

From: Liz Cresto, Technical Hydrologist LC
Matt Anders, Technical Hydrologist MA

Date: March 16, 2015

Subject: Recommended revisions to the Surface Water Coalition Methodology

---

Introduction

On January 30, 2015, the Director of the Idaho Department of Water Resources (IDWR, Department) issued an order to staff directing them to convene a committee of experts to recommend specific technical changes to the "Second Amended Final Order Regarding Methodology For Determining Material Injury To Reasonable In-Season Demand And Reasonable Carryover" (Methodology) signed on June 23, 2010. Department staff created a committee in response to the Director's order composed of IDWR staff and experts representing parties involved in litigation of the Surface Water Coalition's (SWC) 2005 delivery call. In his January 30 order, the Director requested recommendations for technical changes to the Methodology by March 16, 2015, regarding the following specific issues:

1. Revising natural flow forecast methods for Twin Falls Canal Company.
2. Identifying more accurate and current crop data to determine crop water need.
3. Improving the mid-season reasonable in-season demand forecast.

Committee

The committee held multiple meetings and corresponded though email regarding the issues identified in the order. The committee comprises the following members:

Committee Member	Organization	Representing
Charles G. Brockway	Brockway Engineering	Surface Water Coalition
Chuck Brendecke	Lynker Technologies	Idaho Ground Water Users
Dave Shaw	ERO Resources	Surface Water Coalition
David Hoekema	IDWR	IDWR
Greg Sullivan	Spronk Water Engineers	City of Pocatello
Liz Cresto	IDWR	IDWR
Matt Anders	IDWR	IDWR
Scott King	SPF Water Engineering	Idaho Ground Water Users
Sean Vincent	IDWR	IDWR
Sophia Sigstedt	Lynker Technologies	Idaho Ground Water Users

The committee collectively decided that the most efficient method for consolidating member comments while still adhering to the March 16, 2015 deadline was to have committee members attach their comments to this memorandum. All of the committee members had an opportunity to review this memorandum and all of their comments that we received are attached in Appendix B.

Section 1 – Natural Flow Forecast

Background

The Methodology requires the Director to issue an order determining the demand shortfall of the SWC members for the irrigation season. The SWC members include A & B Irrigation District (A&B), American Falls Irrigation District #2 (AFRD2), Burley Irrigation District (BID), Milner Irrigation District (Milner), Minidoka Irrigation District (MID), North Side Canal Company (NSCC), and Twin Falls Canal Company (TFCC). The shortfall is the difference between the forecast supply and the forecast demand for each SWC member. The forecast supply is comprised of two components: the predicted natural flow supply and the predicted storage allocation for each SWC member. Pursuant to the Methodology, the Department undertakes an April forecast and mid-irrigation season forecast.

In the current Methodology, the April predicted natural flow supply is based on a regression analysis comparing the total natural flow in the Snake River near Heise between April and July to the annual natural flow diverted by each SWC member. While the Director only requested revisions to the natural flow forecast recommendations for TFCC, the committee also identified improved models for AFRD2, BID, MID, and NSCC through its work on revised natural flow forecast methods for TFCC. This memo includes recommendations for revising the April predicted natural flow supply forecasts for TFCC, AFRD2, BID, MID and NSCC.

The mid-irrigation season forecast is addressed in Step 6 of the Methodology. The forecast supply in Step 6 is the sum of the actual year-to-date natural flow diverted, plus the predicted natural flow supply for the remainder of the season, plus the actual preliminary storage allocation. The predicted natural flow supply for the remainder of the season was forecast by selecting an analogous year based on the Snake River Blackfoot to Milner reach gains. The selection of the analogous year typically occurred in August and a revised forecasted supply was issued. In working to meet the request of the Director's January 30 order, the committee reviewed a host of models that predict the natural flow supply for each SWC member from July 1 through October 31.

The natural flow supplies for each SWC member are comprised of natural flow in the Snake River passing the near Blackfoot gage and gains which occur in the Snake River between the Blackfoot to Milner reach. The committee reviewed several different models for predicting both the April and mid-season natural flow supply for each SWC member. While many different predictor variables were considered, the following variables were ultimately selected: natural flow in the Snake River near Heise as reported by the U.S. Bureau of Reclamation; snow water equivalent (SWE) data at the Two Oceans Plateau SNOTEL site; Box Canyon Springs discharge; Spring Creek discharge; and groundwater levels near American Falls Reservoir. The recommended model predictors vary by SWC member and by model implementation date (i.e. April 1 vs. July 1) and are summarized in the sections below.

April 1 Forecast

April forecast natural flow supply models were developed using data from 1990 through 2013. Data from 2014 was excluded from model development for two reasons: 1) the dataset for 2014 was still provisional at the time of model development and 2) record rainfall in August of 2014

resulted in significant data anomalies. For these reasons, we decided to exclude 2014 values from the dataset.

Both single linear regression and multiple linear regression models were considered. We recommend that natural flow supply forecast for A&B and Milner continue to be based on single linear regression models, in which the natural flow at the Snake River near Heise is the predictor variable. We believe the natural flow at the Snake River near Heise is a good predictor because A&B and Milner have relatively junior water rights and typically only divert natural flow during the spring runoff events. When applied, the April 1 forecast will utilize the U.S. Army Corps of Engineers and U.S. Bureau of Reclamation joint forecast of total natural flow in the Snake River near Heise from April-July. Alternative models were evaluated, but we found they added additional complexity without significantly improving the existing A&B and Milner models.

New multiple linear regression models are recommended to replace the existing regression models for TFCC, AFRD2, BID, MID, and NSCC. For these entities, the final predictor variables selected for their respective April 1 models included the total April through July natural flow in the Snake River near Heise and the total November to March discharge at Box Canyon Springs. The predictor variable, natural flow in the Snake River near Heise, was considered a good indicator of the natural flow supplied by snowmelt runoff. The predictor variable, Box Canyon Springs, was considered a good indicator for the natural flow supplied by the reach gains in the Blackfoot to Milner reach. If applied, the April 1 forecast models will utilize the U.S. Army Corps of Engineers and U.S. Bureau of Reclamation joint forecast of the natural flow in the Snake River near Heise from April-July.

Below is a table comparing the models used in the current Methodology to the recommended models. The recommended models for each member of the SWC have a better model fit (higher adjusted r^2) and a lower standard error than the models used in the current Methodology.

SWC Member	Models from Current Methodology[1]		Recommended Models	
	Adjusted r^2	Standard Error	Adjusted r^2	Standard Error
AFRD2	0.8317	39,700	0.8448	37,290
BID	0.7964	20,690	0.8546	17,100
MID	0.7896	29,710	0.8786	22,070
NSCC	0.8952	63,580	0.9151	55,950
TFCC	0.5416	71,990	0.8564	37,940

Appendix A contains graphs of the April models in comparison to the actual natural flow diversions for each SWC member.

July 1 Forecast

Step 6 of the Methodology requires the Department to issue a revised forecast supply "approximately halfway through the irrigation season". New natural flow predictor models have been developed for each SWC member for the specific period July 1 – October 31. We recommended that the July 1 models be implemented when revising the forecast supply in Step 6 of the Methodology.

Using data from 1990 to 2013, regression models were developed for A&B, AFRD2, and Milner by comparing snow water equivalent at the Two Oceans Plateau SNOTEL site on July 1 to the total

[1] Final Order Regarding April 2014 Forecast Supply, April 18, 2014.

natural flow diverted for the period July 1 through October 31. Data from 1997 was excluded from model development because of significant data anomalies as of a result of the high runoff year. The snow water equivalent at the Two Oceans Plateau SNOTEL site was considered a good indicator of additional natural flow diversions after July1. Years with zero (0) snow water equivalent on July 1 were excluded from the model dataset. It is recommended that in years with zero (0) snow water equivalent at the Two Oceans Plateau SNOTEL site on July 1, the predicted natural flow supply for the period July 1 – October 31 for A&B, AFRD2, and Milner will also be zero (0). For A&B, AFRD2, and Milner, the regression models would only be used in those years when the July 1 snow water equivalent at the Two Oceans Plateau SNOTEL site is greater than zero.

Multiple linear regression models were developed for BID, MID, NSCC, and TFCC. The regressions for BID, MID, and NSCC were developed with data from 1990 to 2013 and correlations were developed between the total natural flow diversions from July 1 through October 31and three predictor variables: (1) natural flow in the Snake River near Heise (April – June), (2) snow water equivalent at the Two Oceans Plateau SNOTEL site on June 15, and (3) March depth to water at well 05S31E27ABA1. Manual well measurements were historically taken from March 13 to March 30, with an average date of March 23. A transducer installed in May 2010 replaced the need for manual measurements. The combination of historical manual measurements and March 23 transducer readings will be utilized in the models.

The regression model to predict TFCC natural flow diversions from July 1 through October 31 relies on data from 1990 to 2013 and utilizes three predictor variables: (1) natural flow in the Snake River near Heise (April – June), (2) snow water equivalent at the Two Oceans Plateau SNOTEL site on June 15, and (3) Spring Creek total discharge (January – May). Below are summary statistics for the recommended models.

	Regression based on Two Oceans Plateau Snow Water Equivalent		Multiple Linear Regression	
SWC Member	Adjusted R^2	Standard Error	Adjusted R^2	Standard Error
A&B	0.9294	741		
AFRD2	0.8699	7,502		
BID			0.8932	11,480
Milner	0.8382	2,939		
MID			0.9037	15,720
NSCC			0.8615	46,930
TFCC			0.8511	29,270

Appendix A contains graphs of the July predictor models in comparison to the actual natural flow diversions for each SWC member.

Section 2 – Current Crop Mix Data

Current Method

Crop mix is one of the variables used in the current Methodology to calculate the crop water need of the SWC members. Crop mix is defined as the acreage of each crop type grown by each SWC member. The current method for determining crop mix is a three step process:

1) Tabular crop acreages from 1990 to the present are downloaded by county from the USDA National Agricultural Statistics Service (NASS).

2) Based on the tabular data available from 1990 to the present, an average crop mix for each county is determined.

3) The average crop mix of the counties is applied to each SWC member based on the proportion of land the SWC member has in each county.

Shortcomings of the current cropping pattern method include: NASS tabular data is adjusted to protect farmer privacy and is becoming increasing incomplete with fewer acreage totals being reported since 2005, average acreages for a 25-year period do not reflect current crop mix patterns, and county-wide crop mix may not represent the crop mix of SWC members.

Recommended Revision

Based on testing and with consideration of input from the committee, we recommend revising the method for determining crop mix. Instead of relying on county-wide tabular data, we propose using the digital Crop Data Layer (CDL) from the USDA National Agricultural Statistics Service (NASS). Benefits of this proposed method include: (1) using the most recent data available; and (2) restricting the geographic area of the data to the service area of each SWC member. The proposed method would involve the following steps each year:

1) Downloading the digital CDL dataset from the NASS website.

2) Removing crop type classification errors (speckling) in the CDL dataset with Zonal Statics in ArcGIS. A potential source of error associated with the Zonal Statics process is the intermittent availability of an annual field boundary dataset. However, our review of field boundary datasets and historical aerial photography revealed that field boundaries change infrequently and substituting field boundary datasets from previous years introduces minimal error. An additional possible source of error associated with the Zonal Statics process is the assignment of a single crop type to fields actually planted with multiple crop types. With respect to this concern our qualitative review of historical aerial photography and CDL datasets establishes that fields with multiple crops are rare and we conclude this concern represents a minimal source of error.

3) Clipping the CDL dataset in ArcGIS with an irrigated lands dataset for each SWC member.

4) Calculating the acreage by crop type for each SWC member.

5) Computing a 3-year average by crop type for each SWC member. In our analysis we have found the seven years of CDL data that are currently available do not depict a clear relation between cropping pattern and water supply. Because of this finding, a 3-year average appears adequate to reduce the influence of a single year while still being representative of the current cropping pattern.

Our comparison of the results of the tabular and CDL methods establishes that making this revision will cause the percentage of crop types identified for each SWC member to change between 0 and 30 percent (table below). This range of adjustment appears plausible given the change from a 20-year to a 3-year average and from a county-wide geographic area to the service areas of SWC members. A preliminary comparison of the crop water need calculated using the CDL and METRIC indicates the CDL and METRIC are in general agreement.

Section 3- Reasonable In-Season Demand (RISD)

The committee began discussions on improving the mid-season reasonable in-season demand forecast. With the limited timeframe the committee was given, we were unable to conclude an analysis of methods to improve RISD forecasts. Because this analysis is not yet complete, we cannot currently recommend any changes to the current Methodology regarding this issue.

Section 4 – Future Committee Meetings

Committee members provided valuable technical input for revising the Methodology. We recommend continuing to convene this committee in the following manner:

1) At least one annual meeting to review implementation of the Methodology during the previous irrigation season. This would be an ongoing forum for identifying and reviewing potential technical revisions to the Methodology.

2) Multiple meetings during 2015 to finish reviewing the following subjects that were discussed by the committee, but require further discussion and analysis to develop a recommendation:

    a. Mid-season calculation of reasonable in-season demand (RISD): The current method uses average demand in 2006/2008 to predict the RISD for the remainder of the irrigation season. We are analyzing the potential for refining this predication by selecting a representative historical analogous year(s).

    b. Supplemental ground water use: There was insufficient time for the committee to evaluate this subject.

    c. Project efficiency: The project efficiency variable used in the RISD calculation has not been updated since the Methodology was originally developed. The committee had preliminary discussion about the need to update project efficiency and committee members expressed interest in providing input.

    d. Irrigated acres: Significant discussion focused on this topic and it was generally agreed that the process for determining irrigated acres for SWC members could be improved.

APPENDIX B

Comments Received From Committee Members

LYNKER TECHNOLOGIES

MEMORANDUM
Settlement Document Subject to I.R.E 408

To: Liz Cresto

From: Charles Brendecke and Sophia Sigstedt

Subject: Comments on Staff Recommendations

Date: March 16, 2015

This memorandum addresses our comments on the analyses presented to the Technical Working Group related to revisions to the Methodology Order for determining injury to water rights held by members of the Surface Water Coalition. It serves as an addendum to the Idaho Department of Water Resources (IDWR or Department) staff memorandum regarding recommended revisions. Department staff were asked to provide recommendations to the Director on the following topics[1]:

1. Revised natural flow forecast methods for Twin Fall Canal Company (TFCC).
2. Identify more current and accurate crop data to determine crop water need.
3. Improvement of mid-season reasonable in-season demand forecast (RISD).

Topics 1 and 2 were assigned priority and due to time constraints are the only topics the Department staff make recommendations on in their memorandum.

Sections 1 and 2 below summarize our comments based on the proceedings of the committee regarding the recommendations to topics 1 and 2, respectively, in the staff memorandum. It is our understanding that Department staff recommendations on topics 1 and 2 are based on analyses that could be completed within the time constraints provided, and that while they are intended to provide guidance for administration of TFCC's water rights for the 2015 irrigation there will be opportunity for further analyses and recommendations concerning both topics for future irrigation seasons. It is also our understanding further work will be done on topic 3 prior to the need for the mid-season adjustment. Section 3 summarizes our preliminary comments regarding aspects of the mid-season RISD calculation.

The three topics identified above are not the only items in the Amended Methodology Order that were set aside or remanded by the District Court. The comments in our memorandum should not be considered a comprehensive summary of our opinion on all the technical aspects under consideration in the remand of the Amended Methodology Order.

---

[1] Status Conference, January 28th 2015

Section 1

Part D. ofthe Memorandum Decision and Order on Petitions for Judicial Review of the Amended Methodology Order found that "The *Methodology Order's* reliance upon the Joint Forecast, and its use of the Heise Gage, to determine the available water supply for Twin Fall Canal Company is set aside and remanded for further proceedings as necessary." The issue was unopposed and the Department expressed that the Joint Forecast is "not the best evidence" for purposes of predicting TFCC's supply and that they would be willing to work with TFCC to improve the predictors for future application.

The Department staff's recommendations for revised natural flow forecast methods for TFCC began with the assumption that the need to predict TFCC's supply must occur prior to April 1. The comments provided here neither support nor reject that assumption. The Department staff' recommendations for revising TFCC's supply improves the current relationship used in the Methodology Order. However the analysis and committee review process was undertaken in a highly compressed timeframe and many things warrant additional consideration. We support the idea of treating the refinements to the Methodology Order as a "living document" that allows for continual improvement and to use the staff's recommendation as an interim solution for the upcoming 2015 irrigation season only.

We believe that one reason the Heise Gage forecast is not a good predictor for TFCC supply is that the predictor is physically based while the TFCC supply is considered to be the historical TFCC diversion record. TFCC diversions are not the same as the physical supply available to TFCC because the diversions reflect administrative and operational influences in addition to being a condition of the physical natural flow supply. For example, TFCC has the more senior water right relative to the other surface water diverters below Blackfoot and their diversions in early season are often capped by the water right amount rather than the physically available supply. The water right cap creates a non-continuous and non-normally distributed dependent variable in the regression analysis. This difference is a probable reason the Heise forecast alone had such a low correlation to TFCC compared to the other entities. In light of this, an approach that we believe should be further investigated is creating a regression relationship or alternative model that forecasts the physical natural flow supply with subsequent allocation of that physical supply among the rights of the SWC.

The natural flow forecasts for TFCC and subsequently a selection of other entities were improved by moving from a single variable linear regression model to a multilinear regression. The improvement in the TFCC prediction supports the Department staff recommendation in the use of the additional Box Canyon data in April and the Snotel and Spring Creek discharge data in July. The Department Staff also recommended new models for some entities that showed improvement in the July forecast with the addition of Snotel and March groundwater level data. While these newly developed models can be tested over the upcoming irrigation season we believe they can be further improved.

Section 2

Our comments are limited on the succinct issue of the Department staff recommendation to use the digital Crop Data Layer (CDL) from the USDA National Agricultural Statistics Service (NASS) as a more current and accurate crop data source to determine crop water need. One concern here is how the data is post processed. We recommend sensitivity tests to different program settings when raster processing is applied. We also recommend further investigation into the method behind the development of the NASS dataset to determine how and to what extent the data set is field verified or if there are common misrepresentations that should be considered in the process of data quality assurance checks.

Section 3

As the Department memorandum stated there was not sufficient time for the staff to make a recommendation on the RISD forecast. There are multiple components to the RISD forecast calculation that are under review in the current Methodology Order. These include but may not be limited to:

- The mid-season calculation of RISD
- Project efficiency
- Irrigated acres
- Supplemental groundwater use

Regarding the mid-season calculation of RISD the sensitivity and appropriate use of crop coefficients and climate data behind the reference ET in the calculation should be investigated and analyzed for proper application to local conditions.

Regarding project effiencies we recommend investigation into trends among the entities related to each of the factors the Methodology Order considers in their determination.

Regarding irrigated acres it appears there is not a standard review process for the updates by the SWC or for the critique by IDWR of the submittal of the irrigated acres. With only a check against the total acres in the decreed place of use, there is little or no incentive to keep these shapefiles up to date. Based on the discussion in the technical working group the determination of irrigated acres will likely not be addressed in this review process. Updating irrigated acres by verification of claimed irrigated polygons by satellite and/or aerial imagery is a detailed, time consuming process. But it is essential to protect the valid water rights of juniors.

If SWC members are going to be responsible for this task a first step that the Department should take is to develop a standardized method for this update. This should include pointers to the preferred irrigated polygon base layer, satellite/aerial imagery, and a comprehensive list of items that need to be clipped out (i.e. roads, homesteads, brush land, fallow acres, water features, urban areas, sub-divisions), how alignment issues could be improved and recommendations for how to streamline as many of these processes as possible. This process will only be fair if each user does the analysis in the same way. Once a more accurate representation of the irrigated acres for each entity is created and approved updates in the future can be based more on accounting of the movement of water throughout the district as some of the entities already track. The 5% change standard should also be considered in light of large districts like TFCC where a 5% error

in irrigated acres can result in calculation of tens of thousands of acre-feet of erroneous mitigation obligation.

Regarding supplemental groundwater use there was not sufficient time for the working group or Department staff to address this issue. However, it was one of the specific technical items cited for revision by the District Court. Accordingly, we believe that the process that has been established for identifying Methodology revisions be continued until all the technical issues presented in the remand are addressed.

SPF WATER ENGINEERING

MEMORANDUM

DATE: March 16, 2015

TO: Liz Cresto, Technical Hydrologist

FROM: Scott King, P.E., SPF Water Engineering LLC on behalf of IGWA

RE: **Comments on Staff Recommendations**

Job: **535.0190**

Liz,

This memo provides comments to be included with your March 16, 2015 Settlement Document Memorandum.

1. The committee discussed the importance of methodology guidance being a living document and that the Technical Working Group (TWG) should continue meeting occasionally to improve the methodology and address items that were neglected due to limited time. I want to express my support for this approach.

2. Supplemental ground water use was a topic of importance to the Technical Working Group's (TWC), but was not evaluated sufficiently due to time constraints. Supplemental ground water use within much of the surface water coalition's delivery area is measured and reported to IDWR. However, we expect not all ground water use is measured due to the wells being located outside of the ground water measurement program area. Unmeasured supplemental ground water use should be addressed and may need to be measured.

3. The total area of lands receiving surface water irrigation deliveries has been updated for some but not all SWC members. The TWC discussed a methodology whereby irrigated acres would be updated if that area changed more than five percent from currently used values. A five percent change is significantly different when comparing between the smaller and larger delivery entities. For example, five percent approaches ten thousand acres for Twin Falls Canal Company. The committee may consider also including an acreage threshold in this decision point. For example: "the lesser of five percent or one thousand acres." This approach is supported by high quality aerial imagery currently available, limited land use changes within the SWC areas, and prior efforts in identifying and digitizing irrigated and non-irrigated areas.

300 E. Mallard Drive, Suite 350, Boise, Idaho 83706 Tel: 208-383-4140 Fax: 208-383-4156

4. Some delivery entities have reported that irrigated acres are unchanged from decreed values. There is not an incentive for SWC entities to identify and report reductions in irrigated acres. This deficiency should be addressed.

Thank you for the opportunity to participate in the committee and provide these comments.

Memorandum Subject to I.R.E. 408

To: Gary Spackman, Director IDWR

From: Charles G. Brockway, Brockway Engineering on behalf of the SWC
David Shaw, ERO Resources Corp. on behalf of the SWC

Date: March 16, 2015

Re: Recommended Revisions to the Second Amended Final Order Regarding Methodology for Determining Material Injury to Reasonable In-Season Demand and Reasonable Carryover

The SWC generally supports the efforts of the Director, IDWR Staff and other members of the TWG for their efforts and the recommendations proposed in the staff memorandum to the Director dated March 16, 2015. The recommended natural flow forecasting methods and crop mix determination are improvements to the original methodology procedure and we urge the Director to implement those changes. We also support the annual review of the implementation of the Methodology.

In the second paragraph under the April 1 Forecast section the statement is made that A&B and Milner irrigation districts have relatively junior priority water rights and typically only divert natural flow during spring runoff events. We believe it would be worth noting that Milner's priority is good enough to sometimes divert natural flow at other times, particularly late in the irrigation season.

The SWC supports the use of the NASS CDL data to estimate crop mix for the current year based on the 3 previous years' data. We notice in the example on page 6 of the staff memo the average used is for 2011 – 2013. We assume this is the result of a timing issue since the 2014 CDL was not released until after January 1, 2015. We assume the intent is to use the most recent 3 years' data when used to calculate RISD in the Methodology process. We also want to ensure the SWC Managers can submit crop mix data that becomes available to them if they believe any particular year is an anomaly and would not be fairly represented by the previous 3 years' CDL data.

The SWC is concerned about the topics in the final recommendation for multiple meetings for the remainder of 2015. Most of the proposed topics are not part of the Court's remand order. In particular, project efficiency was fully supported by the court in spite of the ongoing efforts by others to attack that aspect of the methodology or the efficiencies themselves. On remand the Court simply said the Director should follow the order when considering irrigated acreage submitted by members of the SWC. We understand the need to change the water supply forecasting methods to make a mid-season determination and the July 1 methods in the staff memorandum address that need but there has not been a compelling reason given to change the method of estimating demand for the remainder of the year.

Again, thank you to everyone who participated and to the Director and his staff for the opportunity to participate in this effort.

Memorandum

To: Matt Anders (Idaho Department of Water Resources)

From: Dave Shaw (ERO Resources), Dave Colvin (LRE Water)

Date: January 16, 2022

Subject: **SWC Response to IDWR Recommended SWC Methodology Updates**

Introduction

On December 23, 2022, Idaho Department of Water Resources (IDWR) staff issued a document summarizing their recommendations for updating the Surface Water Coalition (SWC) Methodology. IDWR presented considerations and potential updates in Technical Working Group (TWG) meetings convened during November and December 2022. The current Methodology was established in the April 19, 2016 IDWR Fourth Amended Final Order Regarding Methodology for Determining Material Injury to Reasonable In-Season Demand and Reasonable Carryover (Fourth Amended Final Order)[1].

The Methodology is intended to protect the maximum reasonable diversion of SWC senior water rights from the in-season impacts caused by junior groundwater pumping. Decades of groundwater pumping effects have reduced the Snake River flows and reduced the water supply for senior water rights creating continuing but variable impacts. This variability creates inherent limitations for the Methodology and has particular significance on the potential updates IDWR presented during TWG meetings.

In addition, the Methodology strives to use predictions and observations to predict reasonable in-season demands (RISD) for SWC entities. Many steps of the Methodology transition from predictive tools early in the season to measured field data later in the season when hydrologic observation data are available. Many of the data, methods, and analyses are insufficient to account for changes in farming practices forced upon SWC entities as a result of economic conditions and water supplies being unreliable throughout the season and year to year.

Despite these fundamental limitations, many aspects of the SWC Methodology represent the best available science for estimating forecasted supply (FS), RISD, and Demand Shortfall (DS). Additional comments on specific IDWR update recommendations are provided below.

1. IDWR Recommended Methodology Updates

a. Baseline Year Update for In-Season Demand and Carryover

IDWR is recommending that the Baseline Year (BLY) be updated to 2018. The process for selecting the BLY is described in the Fourth Amended Final Order and identifies both 2018 and 2020 as candidate baseline years. Based on the additional years of data considered since the Methodology was developed, both 2018 and 2020 are superior to the current baseline years (2006, 2008, 2012) which are no longer acceptable candidates. IDWR's rationale for only selecting 2018 is that 2020 had relatively high late-season diversions for the Twin Falls Canal Company (TFCC). Estimates of late-season project efficiency are higher in 2020 than in 2018, indicating that the late-season TFCC diversions, although higher, are reasonable. Changes in late season demands are being driven by economic conditions and the dairy industry's need for feed that has resulted in double cropping and changes in harvest methods. Double cropping is sometimes triticale followed by field corn resulting in later season water demands to finish the corn. Other examples are alfalfa harvested as green chop instead of baled hay so the crop water requirement is continual instead of allowing time for the crop to dry in the field so it can be baled. In the past hay crops were often 3 cuttings per year but now are 5 or more cuttings that create additional crop water needs, particularly late irrigation season demands. Additionally, late season irrigation is sometimes required for cover crops or late season ground working in preparation of fall seeding that is likely not reflected by AgriMet Et data.

A review of CWN data for the period 2000 – 2022 shows an increase over time that has, in part, resulted in the need to select a new BLY for determining an adequate water supply for the SWC. If the current methodology is continued, a regular review of the BLY is recommended as provided in Step 9 of the Methodology Order. Along with changes in CWN, a review of NASS crop data layers (CDL) should be completed to verify the crop mix present on the land served by the SWC if the use of METRIC is not implemented.

The selection of a new BLY is expected to increase the total reasonable carryover quantities for most of the SWC members. Step 8 in the Methodology Order needs to be reviewed to be certain the new reasonable carryover quantities can actually be replaced by the junior ground water users if the SWC members' reasonable carryover is used to finish the season at the Time of Need.

b. Update Project Efficiency Values

Central to proper determination of project efficiency is an accurate determination of CWN. As climate conditions and cropping patterns change, the determination of CWN needs to

be kept current with conditions in the field. AgriMet is a significant resource so long as the results are adapted to current cropping patterns and field conditions.

Using a 15 year rolling average for current year reasonable project efficiency instead of the present 8 year rolling average does not appear to change the current year efficiencies significantly. As the available record of Project Efficiencies continues to grow, using the longer 15 year rolling average may have advantages, but may need to be reviewed again in the future.

2. IDWR TWG Topics Not Being Recommended for Methodology Updates

In their December 23, 2022 letter, IDWR staff identified issues that were discussed during the TWG meetings that are not being recommended as updates to the SWC Methodology.

a. Real-time METRIC data for determining crop water need

IDWR staff presented information about the potential benefits of utilizing real-time METRIC and PRISM data for determining crop water need (CWN). These data sources are spatially variable estimates of evapotranspiration (ET) and precipitation, respectively. They would likely better represent the variability of ET and precipitation across SWC entities compared to the current methods which are based on ET and precipitation data observed at two AgriMet stations.

It is our opinion that IDWR should continue to evaluate the benefits of incorporating real-time METRIC and PRISM data into estimating actual CWN. Other available data, including OpenET, should be considered as well.

b. April and July Natural Flow Regressions

During the TWG meetings, IDWR presented information about the performance of variables originally selected to support April and July FS predictions. Additional data from 2016-2021 were added to evaluate the performance of the predictor variables as measured by the correlation coefficient comparing predictions to actual natural flow. In summary, no significant degradations in predictive capability were identified, so there is no recommendation to change this aspect of the Methodology. Other candidate predictor variables should continue to be assessed and considered for incorporation should their performance prove better than the current inputs.

c. Transient ESPAM Modeling

During the November 28, 2022 TWG meeting, IDWR staff presented an analysis comparing steady state and transient uses of the Eastern Snake Plain Aquifer Model Version 2.2 (ESPAM) for determining curtailment dates under the Methodology. No TWG meeting attendees stated that they remembered the original rationale for steady-state modeling, including IDWR staff.

Steady-state modeling of groundwater curtailment predicts the maximum impacts that would occur over infinite time. There is no time variable result that relates to the irrigation season. In reality, the impacts of curtailment take time to propagate through the aquifer and occur over months, years, or decades depending on variables such as the distance of a well from the river, and the aquifer transmissivity between the two.

Transient and steady-state versions of ESPAM were created to support various administration and planning efforts by IDWR and Eastern Snake Plain Aquifer (ESPA) stakeholders interested in evaluating the interaction between surface water and groundwater. Steady-state versions of the model are used when results showing ultimate impacts without regard to time are desired. Transient ESPAM versions are used when results require time variable inputs (e.g. pumping limited to the irrigation season) or outputs (e.g. reach gain impacts during a single irrigation season).

Because the Methodology is intended to address in-season injury, transient modeling analysis is the only appropriate way to determine curtailment dates that would protect SWC water rights and supplies. IDWR presented the steady state versus transient differences between ESPAM predicted in-season impacts of curtailment as increases in near Blackfoot to Minidoka reach gains during the 2021 and 2022 seasons. IDWR showed that the transient ESPAM model predicts an October 11, 1900 curtailment date would result in 97,700 acre-foot (AF) impact in the April to September period. Steady-state modeling of the same curtailment date predicts approximately 1,100,000 AF of impact accruing instantaneously as reach gain increases. The steady-state result is clearly erroneous and overpredicts the in-season benefits of curtailment by more than an order of magnitude.

IDWR staff also presented the impact of curtailment in future years beyond the in-season benefits. Future years with relatively low natural flow would provide SWC benefits from the increased reach gains. Years with higher natural flows, when storage fills, would not directly benefit SWC as reach gain increases. IDWR speculated that these wet years would possibly result in increased flow past Milner or provide additional water for managed aquifer recharge. Utilizing the current recharge sites would not significantly

increase near Blackfoot to Minidoka reach gains and therefore would provide limited benefit to SWC water supplies.

IDWR's modeling analysis conclusions stated that "*Short-term curtailments in response to in-season predictions of DS [Demand Shortfall] are inadequate to provide water during the time of need for several of the shortfall volumes predicted in 2021-2022*." This conclusion highlights the multi-year challenges that the Methodology is currently incapable of addressing.

Curtailment required by the Methodology is only applicable to junior groundwater users not covered in a settlement agreement or mitigation plan. The current agreements between SWC and ESPA groundwater users acknowledge the multi-year aspects of injury. IDWR's modeling results and the existing settlement agreements recognize the need for more effective protection of SWC's water supplies. Other Methodology steps are adjusted to create conservative results that protect senior surface water supplies, and the same approach should be taken with the modeling of curtailment dates.

Currently, the only aspect of the Methodology that has an impact year to year is the calculation of Reasonable Carryover. Although it is unlikely to be sufficient to protect SWC water supplies in all years, the Reasonable Carryover calculation could be increased to consider the inadequacies of curtailment for meeting in-season shortfalls. Ultimately, a comprehensive administration approach will need to fully address the multi-year nature of junior groundwater pumping on senior surface water supplies.

BEFORE THE DEPARTMENT OF WATER RESOURCES

OF THE STATE OF IDAHO

IN THE MATTER OF THE DISTRIBUTION OF WATER TO VARIOUS WATER RIGHTS HELD BY AND FOR THE BENEFIT OF A&B IRRIGATION DISTRICT, AMERICAN FALLS RESERVOIR DISTRICT #2, BURLEY IRRIGATION DISTRICT, MILNER IRRIGATION DISTRICT, MINIDOKA IRRIGATION DISTRICT, NORTH SIDE CANAL COMPANY, AND TWIN FALLS CANAL COMPANY	Docket No. CM-DC-2010-001 **FIFTH AMENDED FINAL ORDER REGARDING METHODOLOGY FOR DETERMINING MATERIAL INJURY TO REASONABLE IN-SEASON DEMAND AND REASONABLE CARRYOVER**

BACKGROUND

On April 19, 2016, the Director ("Director") of the Idaho Department of Water Resources ("Department") issued his *Fourth Amended Final Order Regarding Methodology for Determining Material Injury to Reasonable In-Season Demand and Reasonable Carryover* ("Fourth Methodology Order"). The Fourth Methodology Order: (1) explained how the Director would determine material injury to storage and natural flow water rights of members of the Surface Water Coalition ("SWC")[1]; (2) established methods for quantifying material injury to SWC storage and natural flow water rights as predictive and actual demand shortfalls; (3) established methods for quantifying mitigation obligations by holders of junior priority ground water rights for shortfalls in predictive and actual SWC water demands; and (4) established a method for determining a priority date for curtailment if mitigation obligations are not satisfied.

The processes established in the Fourth Methodology Order for determining material injury are not carved in stone. Updates to the methodology order based on additional data and analyses were always anticipated:

> Recognizing his ongoing duty to administer the State's water resources, the Director should use available data, and consider new analytical methods or modeling concepts, to evaluate the methodology. As more data is gathered and analyzed, the Director will review and refine the process of predicting and evaluating material injury. The methodology will be adjusted if the data supports a change.

[1] The SWC is comprised of A&B District, American Falls Reservoir District #2, Burley Irrigation District, Milner Irrigation District, Minidoka Irrigation District, North Side Canal Company, and Twin Falls Canal Company. Each entity holds separate senior surface natural flow water rights and has separate storage contracts for storage water space in the reservoirs.

Fourth Methodology Order, Conclusion of Law 17; *see also In Matter of Distribution of Water to Various Water Rts. Held By or For Ben. of A & B Irrigation Dist.*, 155 Idaho 640, 645, 315 P.3d 828, 833 (2013) ("[t]he concept of a baseline is that it is adjustable . . . ."). The prediction and determination of rights and obligations of the holders of senior priority and junior priority water rights respectively must: (1) apply the best available science and underlying water data; (2) consider changing climatic and cropping patterns; and (3) adhere to the most recent decisions of the courts related to water administration.

Many of the data sets the Department relied upon in the Fourth Methodology Order have been expanded and now include additional years. Furthermore, the Department now has multiple years of experience with the methodology to better understand the impact of applying steady-state modeling versus transient modeling to determine a curtailment priority date that would supply adequate water to the senior water right holders. The first version of the ESPA groundwater flow model was not calibrated at a time-scale that supported in-season transient modeling. In contrast, the current version was calibrated using monthly stress periods and half-month time steps, a refinement that facilitates in-season transient modeling for calculating the response to curtailment of groundwater use. The purpose of this *Fifth Amended Final Order Regarding Methodology for Determining Material Injury to Reasonable In-Season Demand and Reasonable Carryover* ("Fifth Methodology Order") is to update the Director's methodology for determining material injury to storage and natural flow water rights either held by or committed to members of the SWC consistent with the Director's ongoing obligation to use the best available science and information.

FINDINGS OF FACT

I. Overview of the Methodology for Determining Material Injury to Water Rights by Determining Reasonable In-Season Demand and Reasonable Carryover

1. The methodology for determining material injury to water rights by determining reasonable in-season demand ("RISD") and reasonable carryover should be based on updated data, the best available science, analytical methods, and the Director's professional judgment as manager of the state's water resources. In the future, climate may vary and conditions may change; therefore, the methodology may need to be adjusted to consider a different baseline year or years ("BLY") or changes to other components.

2. In-season demand shortfall ("IDS") will be computed by subtracting RISD from the forecast supply ("FS"). In-season demand shortfall is computed using the following equation:

$$IDS = FS - RISD$$

3. If the FS is greater than the RISD, there is no demand shortfall. If the FS is less that the RISD, the negative difference is the demand shortfall. Initially, RISD is equal to the historic demands associated with a BLY as selected by the Director, but will be corrected during the season to account for variations in climate and water supply between the BLY and actual conditions.

4. Reasonable carryover shortfall will be computed by subtracting reasonable carryover from actual carryover, where reasonable carryover is defined as the difference between a baseline year demand ("BD") and projected typical dry year supply. Reasonable carryover shortfall will be computed using the following equation:

Reasonable Carryover Shortfall = Actual Carryover – Reasonable Carryover

5. If actual carryover exceeds the reasonable carryover, there is no reasonable carryover shortfall. In contrast, if reasonable carryover exceeds the actual carryover, the negative difference is the reasonable carryover shortfall.

6. The concepts underlying the selection of the BLY, determination of in-season demand shortfall, and reasonable carryover shortfall will be discussed in detail below.

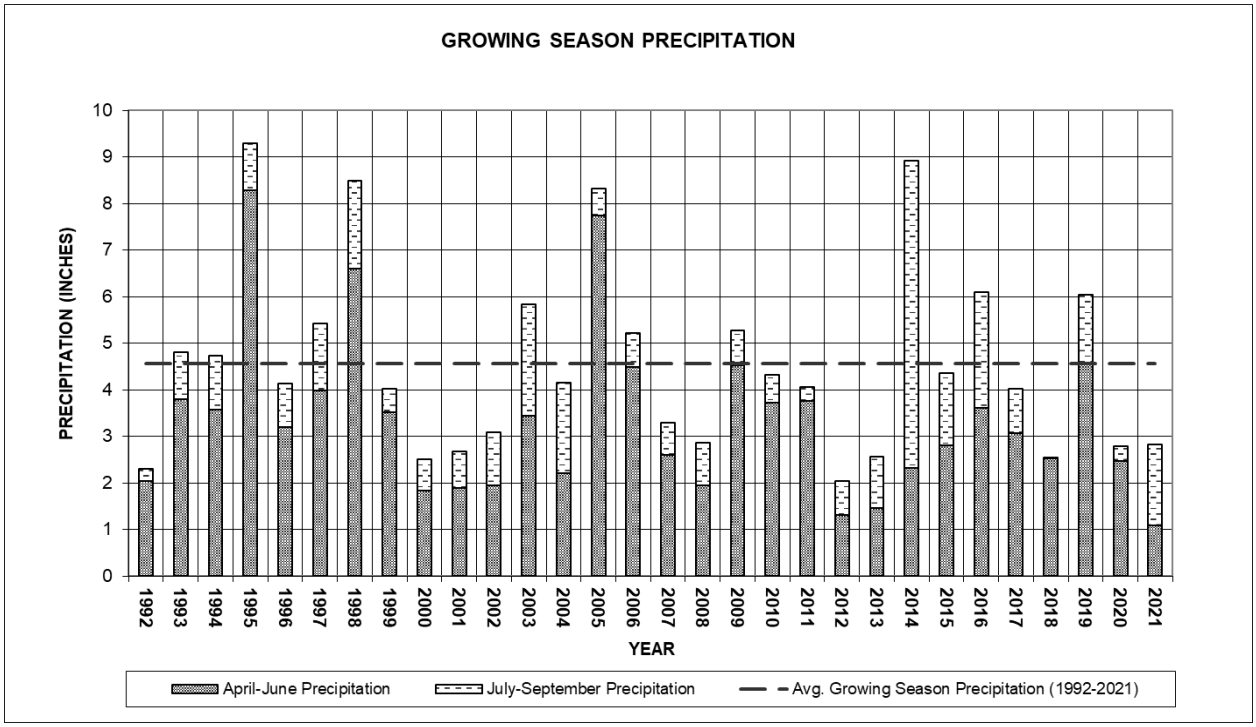
II. In-Season Demand Shortfall

A. Considerations for the Selection of a Baseline Year

7. A BLY is a year or average of years when irrigation demand represents conditions that can predict need in the current year of irrigation at the start of the irrigation season. The purpose of predicting need is to estimate material injury.

8. A BLY is selected by analyzing three factors: (1) climate; (2) available water supply; and (3) irrigation practices. R. Vol. 37 at 7098.[2] To capture current irrigation practices, identification of a BLY is limited to years subsequent to 1999. *Id*. at 7096.

9. The historic diversion volumes from the BLY and the predicted supply forecast at the start of the irrigation season are inputs to predict the initial ISD, where a demand shortfall is the difference between the BD and the FS. When the difference is a negative number, the ISD is zero. ISD increases with increases in BD, decreases in FS, or both. Assuming constant irrigation practices, crop distributions, and total irrigated acres, demand for irrigation water typically increases in years of higher temperature, higher reference evapotranspiration ("ET"), and lower precipitation. If water demand data is averaged for several years and these averages are the basis to predict demand shortfall at the start of the season, in a high-water demand year, these averages may often under-predict the demand shortfall. In a high-water demand year, under-prediction of IDS might be acceptable if the junior priority ground water right holders and the senior priority surface water right holders shared equally in the risk of water shortages. Equality in sharing the risk will not adequately protect the senior priority surface water right holder from injury. Actual demand shortfalls to a senior surface water right holder resulting from predictions at the start of the irrigation season based on average data unreasonably shifts the risk of shortage to the senior surface water right holder. Therefore, a BLY should represent a



[2] All citations in this Order are to material that was admitted during the original hearing and is part of the final agency record on appeal in Gooding County Case No. CV-2008-551, which was lodged with the Fifth Judicial District Court on February 6, 2009.

year(s) of above average diversions and should not represent a year(s) of average or below average diversions. An above average diversion year(s) selected as the BLY should also represent a year(s) of above average temperatures and reference ET, and below average precipitation to ensure that increased diversions were a function of crop water need and not other factors. In addition, actual supply should be analyzed to assure that the BLY is not a year of limited supply.

i. Climate

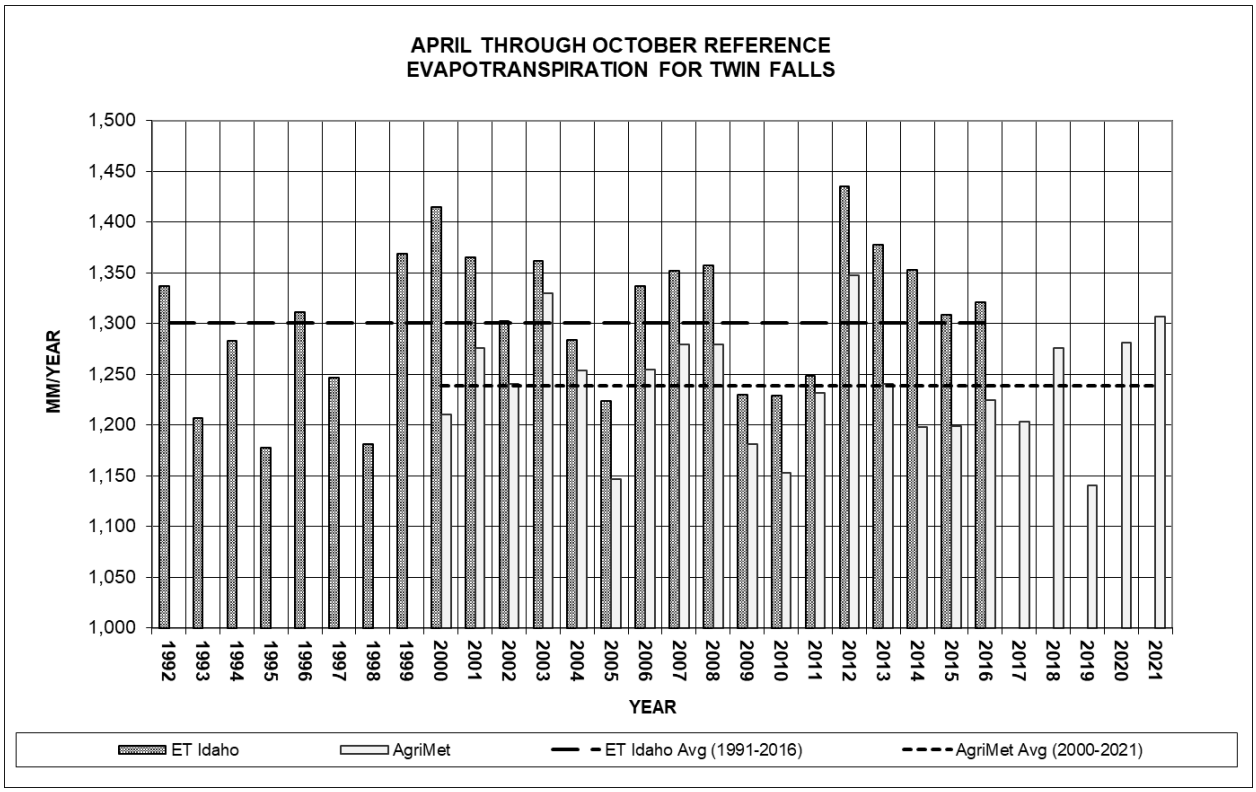
10. For the methods outlined herein, climate is represented by precipitation, reference ET, and growing degree days.

11. Precipitation. Water, in all phases, introduced to Idaho from the atmosphere is termed precipitation. During the growing season, precipitation reduces the irrigation water needed for growing crops. Ex. 3024 at 19. The figure below shows the precipitation recorded during the growing season at the National Weather Service's Twin Falls weather station.

Growing Season Precipitation at National Weather Service's Twin Falls Weather Station 1992–2021.[3]

[3] The Fourth Methodology Order included data for the period 1990 through 2014. This Fifth Methodology Order updates this chart with data for the period 1992 to 2021. The chart is created from NOAA National Weather Service total precipitation data obtained from the NCDC's Climatological Data Annual Summary Idaho report series for the Twin Falls 6 E and Twin Falls Sun Valley Regional Airport weather stations.

12. Evapotranspiration. ET is a variable representing both the amount of water that transpires from vegetation and the amount of water that evaporates from the underlying soil. ET is an important factor for properly estimating RISD. In its water budget calculations, the SWC proposed the use of ET values from the USBR as part of their Pacific Northwest Cooperative Agricultural Network, i.e. AgriMet. Ex. 8000, Vol. II, Chap. 9; Ex. 8000, Vol. IV, Appdx. AU. The ground water users proposed the use of ET values from Richard G. Allen and Clarence W. Robison 2007, Evapotranspiration and Consumptive Irrigation Water Requirements for Idaho, i.e. ETIdaho. Ex. 3007A at 21; Ex. 3024 at 1-58.



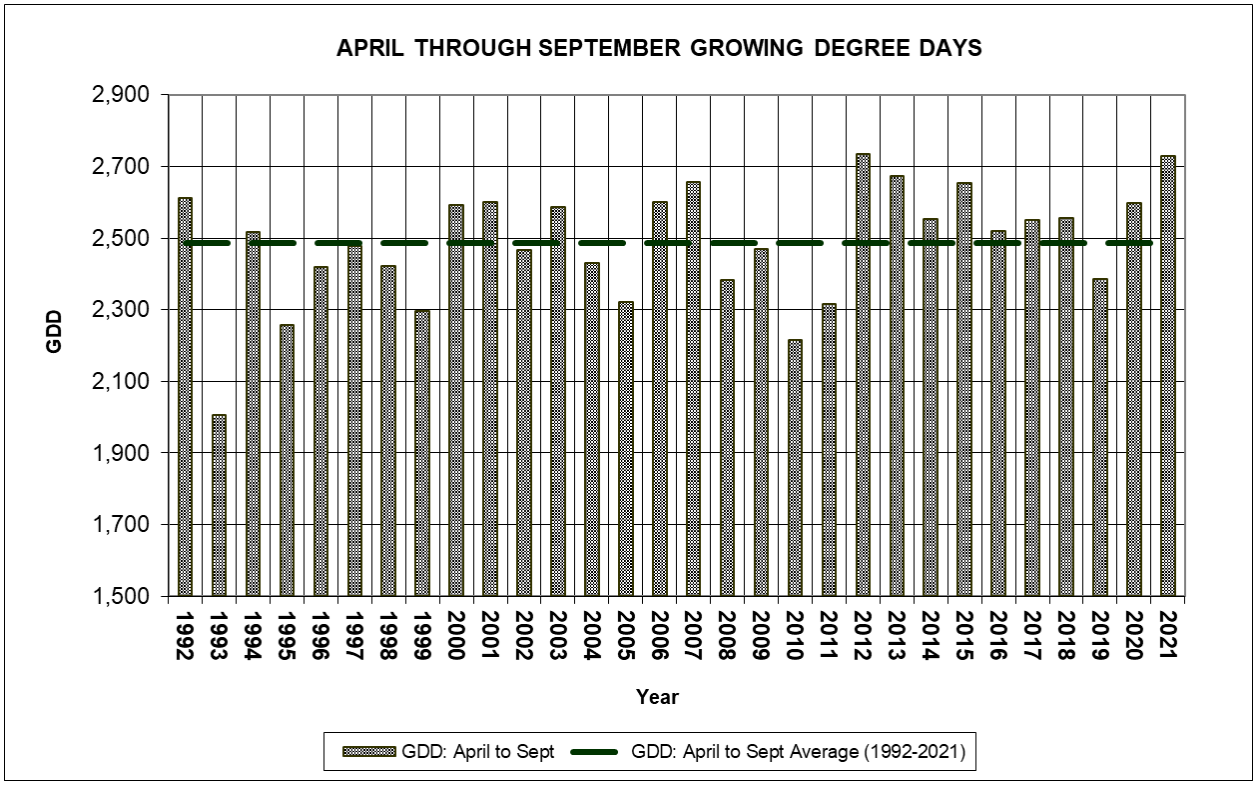
13. Reference ET is a standardized index that approximates the climatic demand for water vapor (i.e. ET). Both ETIdaho and AgriMet calculate and publish reference ET data. The Department will identify potential BLYs by consulting both ETIdaho reference ET and AgriMet reference ET.

14. Neither ETIdaho reference ET data nor AgriMet reference ET data span the entire period of analysis (1992-2021). ETIdaho reference ET data are currently available from 1990 through 2016.[4] AgriMet reference ET data are available from 2000 to 2021.[5] Ideal BLY candidates are years in which reference ET exceeds average reference ET values. The individual year is compared using both AgriMet and ETIdaho reference ET data for those years in which both data are available and only AgriMet data in those years where there is no ETIdaho data.

[4] The Fourth Methodology Order included ETIdaho reference ET data for the period 1991 to 2011. ETIdaho reference ET data is now available through 2016. This Fifth Methodology Order updates this chart with data for the period 1992 to 2016.

[5] The Fourth Methodology Order included AgriMet reference ET data for the period 2000 to 2014. . AgriMet reference ET data is now available through 2021. This Fifth Methodology Order updates this chart with data for the period 2000 to 2021.

15. Years of above average values of reference ET are appropriate BLY candidates.[6] Total April through October reference ET for the period of record from the Twin Falls (Kimberly) AgriMet site is shown below.

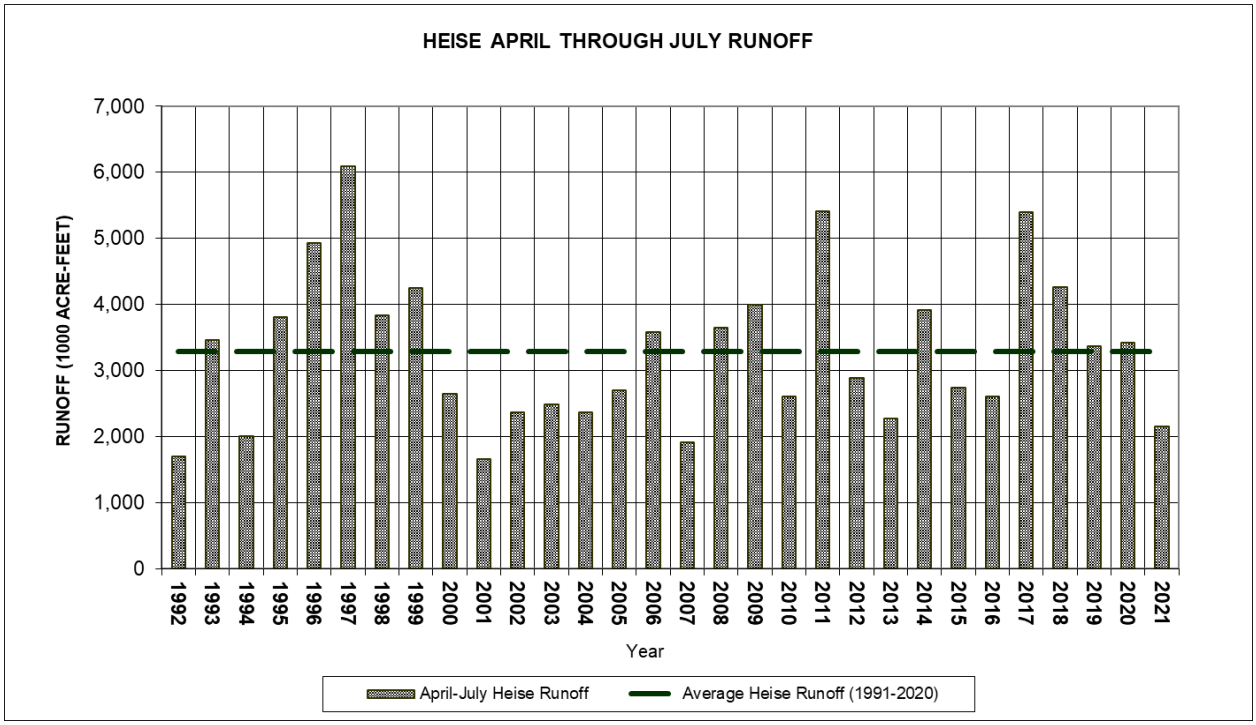


Reference ET for Twin Falls (Kimberly) with both AgriMet and ETIdaho data 1992-2021.[7]

[6] Values for reference ET between ETIdaho and AgriMet do not match because they are derived differently. The relevant information for identifying a potential BLY is the relationship between the year under consideration and the average for the data sets.

[7] The Fourth Methodology Order included data only through 2014. This Fifth Methodology Order updates this chart with combined data for the period 1992 to 2021, establishing a 30-year record which is the professional standard of practice for calculating climatic and hydrologic normals.

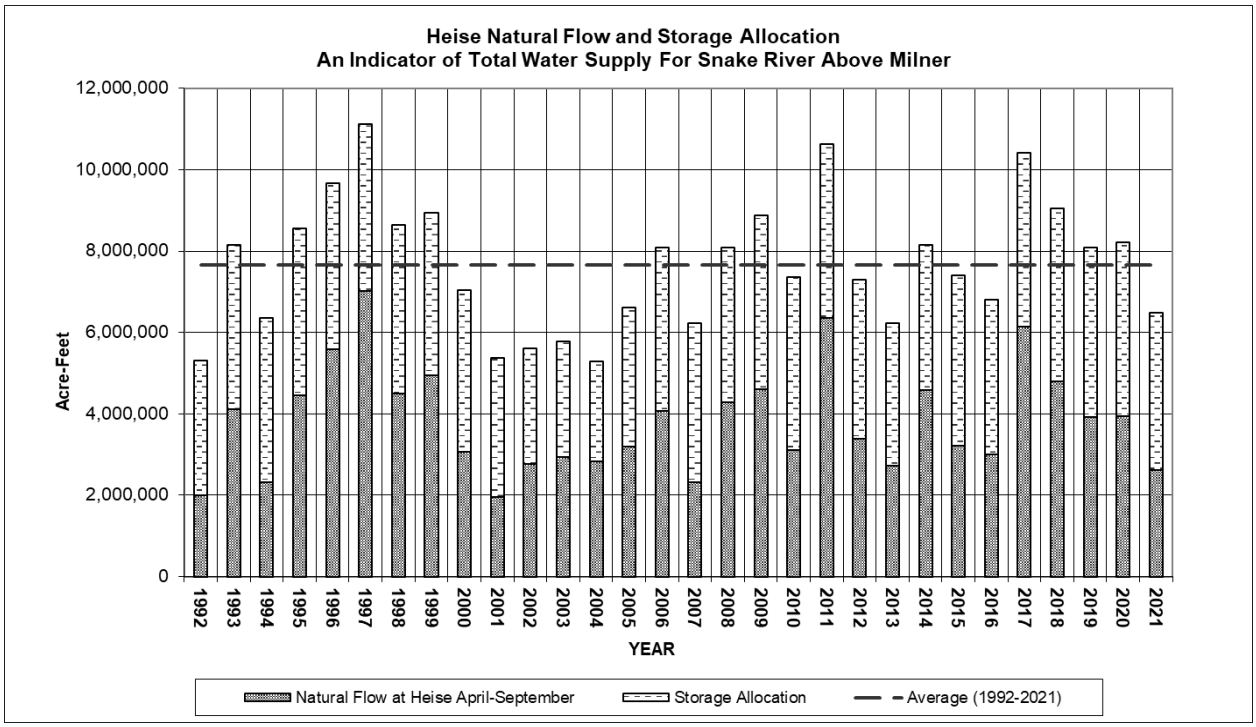
16. Growing Degree Days. Growing degree days define the length and type of growing season. Growing degree days are an arithmetic accumulation of daily mean temperature above a certain base temperature. Ex. 3024 at 10; 117-21. These growth units are a simple method of relating plant growth and development to air temperatures. Different plant species have different base temperatures below which they do not grow. At temperatures above this base, the amount of plant growth is approximately proportional to the amount of heat or temperature accumulated. A higher annual growing degree day value correlates to a higher potential rate of plant growth. The table below shows growing degree days accumulated for April through September for the Twin Falls (Kimberly) AgriMet site.



Growing Degree Days ("GDD") for Twin Falls (Kimberly) AgriMet Site 1992-2021.[8]

[8] The Fourth Methodology Order included data only through 2014. This Fifth Methodology Order updates this chart with data for the period 1992 to 2021.

ii. Available Water Supply



17. The April through July Heise runoff volume represents the volume of water available for diversion into storage reservoirs and is an indicator of natural flow supplies. The graph below shows actual unregulated flow volumes at Heise for 1992 through 2021. The 1992 to 2021 average (3,284,000 acre-feet) is displayed by the dashed line.

April through July Unregulated Flow Volume at Heise, 1992-2021.[9]

[9] The Fourth Methodology Order included data only through 2014. This Fifth Methodology Order updates this chart with data for the period 1992 to 2021.

18. The sum of the Heise natural flow and the reservoir storage allocations is an indicator of the total supply of the Snake River. The sum of the Heise natural flow and reservoir storage allocations for each year from 1992-2021 is represented in the graph below.

The sum of the Heise natural flow and the storage allocation for the Snake River above Milner 1992-2021.[10]

iii. Irrigation Practices

19. A baseline year ("BLY") must be recent enough to represent current irrigation practices. R. Vol. 37 at 7099-7100. Current conditions should be represented by: (a) the net area of the irrigated crops, (b) farm application methods (flood/furrow or sprinkler irrigation), and (c) the conveyance system from the river to the farm. The type of sprinkler systems should be similar between the BLY and the current year.

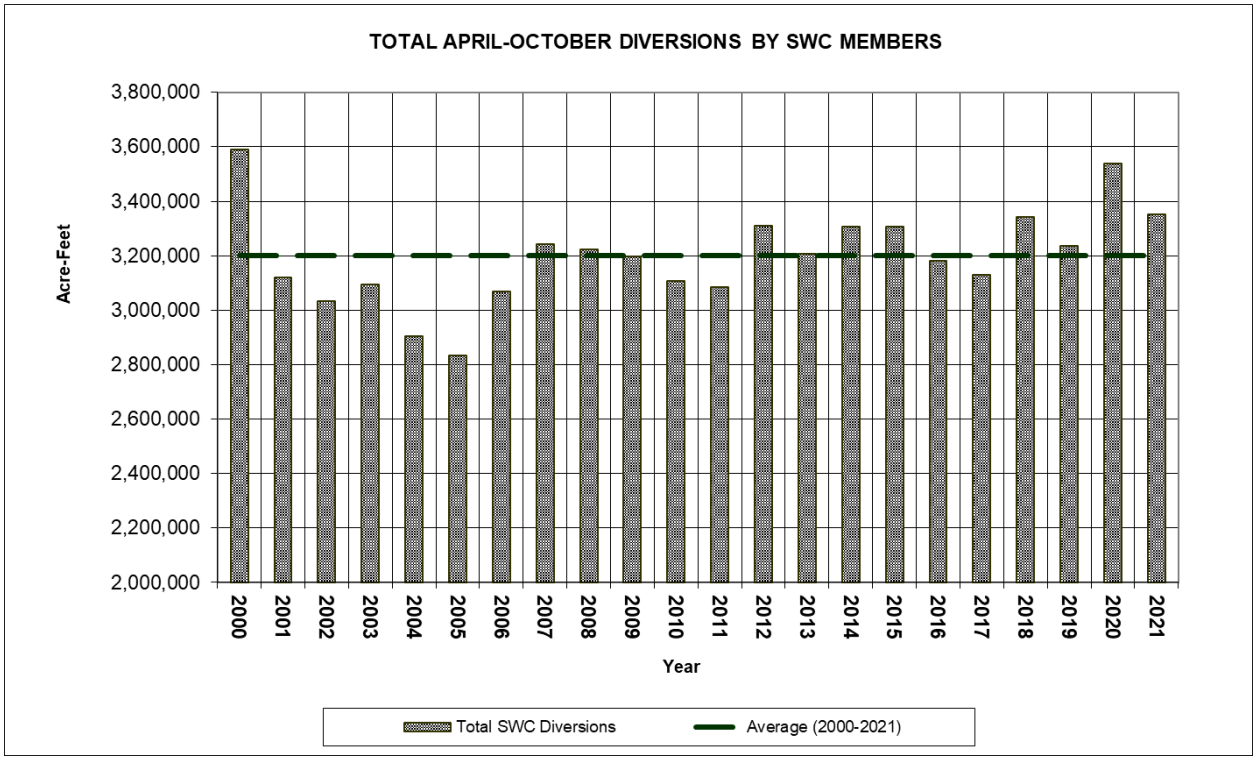
20. Sprinkler systems are currently the predominant application system. *Id*. at 7101-02. To ensure that current irrigation practices are captured, selection of a BLY for the SWC should be limited to years subsequent to 1999. *Id*. at 7096; 7099-7100.

[10] The Fourth Methodology Order included data for the period 1990 to 2014. This Fifth Methodology Order updates this chart with data for the period 1992 to 2021.

21. Estimates of irrigated acres from the hearing show a trend of decreasing irrigated acreage. R. Vol. 28, 5205-15; R. Vol. 37 at 7100. According to the Hearing Officer, beneficial use cannot occur on acres that have been hardened or are otherwise not irrigated. R. Vol. 37 at 7100.

22. The following table summarizes: a) SWC entities; b) shapefile source of reported irrigated acres; c) year shapefile created; d) decreed irrigated acres; (e) number of reported acres in shapefile; and f) irrigated acres used in this methodology order for the 2023 irrigation season. The number of irrigated acres used in this methodology order is the number of reported acres unless that number is larger than the decreed irrigated acres, and if so, then the decreed acres were used. This table will be updated annually based on the reported number of irrigated acres by each SWC entity in Step 1 of the Methodology Order.

Entity	Shapefile Source	Shapefile Year	Partial Decree Acres	Shapefile Acres	Acres Used in Methodology
A&B	PPU[1]	2010	15,924	21,972	15,924
AFRD2	PPU	2010	62,361	69,077	62,361
BID	SWC	2013	47,643	46,035	46,035
Milner	PPU	2010	13,335	13,264	13,264
Minidoka	SWC	2023	75,093	77,176	75,093
NSCC	PPU	2010	154,067	224,463	154,067
TFCC	SWC	2013	196,162	194,732	194,732



[1] IDWR permissible place of use.

Acres used in the methodology.

23. There are lands within the service areas of SWC entities that are irrigated with supplemental groundwater. Exhibit 3007. Supplemental groundwater is a factor the Director can consider in the context of a delivery call. *Memorandum Decision and Order on Petitions for Judicial Review* ("Methodology Remand Order") in Gooding County Consolidated Case No. CV-2010-382, at 18-19. At this time, the information submitted or available to the Department is insufficient to determine the extent of supplemental irrigation on lands within the service areas of SWC entities.

iv. Diversions

24. The following figure summarizes the annual measured diversions by the combined SWC members from 2000-2021. Diversions for a baseline year should exceed the average diversions.

Total April-October Diversions by SWC Members.[11]

B. Selection of the Initial Baseline Year

25. When selecting the BLY the Director must evaluate recent data to determine whether the BLY section criteria are satisfied.

26. In the Fourth Methodology Order, the Department considered the years 2000-2014 when deciding the BLY. Ultimately, the Department chose an average of the years 2006, 2008, and 2012 for the BLY ("BLY 06/08/12"). For this Fifth Methodology Order, the years 2000-2021 were considered for the BLY selection. With the addition of new data from 2014 to 2021, the total diversions by the SWC for the previous BLY 06/08/12 are 100% of the average SWC diversions for the years 2000-2021. As a result of adding the new data, BLY 06/08/12 no longer satisfies the presumption criteria that total diversions in the BLY should exceed the average annual diversions. Mem. Decision & Order on Pets. for Jud. Rev., at 34, *IGWA v. Idaho Dep't of Water Res.*, No. CV-2010-382 (Gooding Cnty. Dist. Ct. Idaho Sept. 26, 2014).

[11] The Fourth Methodology Order did not include this chart. It was added to demonstrate that the baseline year is a year of above average total diversions.

27. Years 2018 and 2020 satisfy all the BLY selection criteria discussed above. Each of these years had (1) total diversions above the average diversions for the years 2000-2021, (2) total growing degree days above the average for the years 1992-2021, and (3) reference ET values above the average for the years 1992-2021. The years 2018 and 2020 also had total precipitation values below the average precipitation for the years 1992-2021 and were not water supply limited years. The Department has reviewed the SWC's diversion data for the 2020 irrigation season. The Department finds that 2020 ranks as the second-highest year of total diversions for the SWC and is more than one standard deviation above the average for the years 2000-2021. In comparison, 2018 ranks as the fourth-highest year of total diversions for the SWC and is less than one standard deviation above the average for the years 2000-2021. Choosing a BLY with above average diversions but within one standard deviation, ensures that a conservative year is selected that protects the senior while excluding extreme years from consideration. The Director concludes that total diversions for 2018 adequately protect senior water rights when predicting the demand shortfall at the start of the irrigation season and selects 2018 as the BLY.

Entity	2000-2021 Avg. Total Diversions (Acre-Feet)	06/08/12 Avg. Total Diversions (Acre-Feet)	06/08/12 % of Avg.	2018 Total Diversions (Acre-Feet)	2018 % of Avg.
A&B	59,474	59,993	101%	64,192	108%
AFRD2	427,978	427,672	100%	453,890	106%
BID	247,049	251,531	102%	262,211	106%
Milner	53,343	47,135	88%	58,417	110%
Minidoka	354,181	369,492	104%	354,851	100%
NSCC	996,267	978,888	98%	1,026,661	103%
TFCC	1,062,098	1,060,011	100%	1,121,717	106%
Total	3,200,389	3,194,722	100%	3,341,939	104%

Average SWC Diversions (acre-feet) for 2000-2021, 2006/2008/2012 BLY, and 2018 BLY.

C. Calculation of Reasonable In-Season Demand

28. Reasonable in-season demand (RISD) is the projected annual diversion volume for each SWC entity during the year of evaluation that is attributable to the beneficial use of growing crops within the service area of the entity. Given that climate and system operations for the year being evaluated will likely be different from the BLY, the BLY must be adjusted for those differences. As stated by the Hearing Officer, "The concept of a baseline is that it is adjustable as weather conditions or practices change, and that those adjustments will occur in an orderly, understood protocol." R. Vol. 37 at 7098.

i. Project Efficiency

29. Project efficiency ("E_p") is the ratio of total volumetric crop water needs within a SWC entity's boundary and the total volume of water diverted by that entity to satisfy its crop needs. It is the same concept as system efficiency, which was presented at hearing. Ex. 3007 at

28-29. Implicit in this relationship are the components of seepage loss (conveyance loss), on-farm application losses (deep percolation, field runoff), and system operational losses (return flows) for which data is not obtainable by the Department. By utilizing project efficiency and its input parameters of crop water need and total diversions, the influence of the unknown components for which data is not obtainable can be captured and described without quantifying each of the components. Project efficiency is derived by dividing crop water need by total diversions as depicted in the algorithm below:

$$E_p = \frac{CWN}{Q_D}$$

Where:

E_p = project efficiency,
CWN = crop water need, and
Q_D = irrigation entity diversion of water specifically put to beneficial use for the growing of crops within the irrigation entity.

30. Monthly SWC entity diversions ("Q_D") will be obtained from Water District 01's diversion records. Ex. 8000, Vol. II, at 8-4, 8-5. Raw monthly diversion values will then be adjusted to remove any water diversions that can be identified to not directly support the beneficial use of crop development within the irrigation entity. Examples of adjustments include the removal of diversions associated with in-season recharge and diversion of irrigation water on the behalf of another irrigation entity. Adjustments are unique to each SWC member and each irrigation season and will be evaluated each year. Any natural flow or storage water deliveries to entities other than the SWC for purposes unrelated to the original right will not be included as a part of the SWC water supply or carryover volume. Water that is purchased or leased by a SWC member may become part of the shortfall obligation to the extent that member has been found to have been materially injured. *See e.g.* R. Vol. 38 at 7201, n. 11 (Eighth Supplemental Order). Conversely, water supplied to private leases or to the rental pool by a SWC member will be included as a part of the SWC supply for that member because non-inclusion would unjustifiably increase the shortfall obligation.

31. Monthly project efficiencies will be computed for the entire irrigation season. Project efficiency varies from month-to-month during the season and will typically be lower during the beginning and ending of the season. Monthly project efficiencies will be divided into actual monthly crop water need ("CWN") values to determine RISD during the year of evaluation.

32. In the Fourth Methodology Order, project efficiencies for each SWC member were initially averaged over an eight-year period (2007-2014) and project efficiency greater or less than two standard deviations were excluded from the calculation. By including only those values within two standard deviations, extreme values from the data set are removed. Under the Fourth Methodology Order, an updated 8-year rolling average of project efficiencies was calculated each year the methodology was implemented. The Director now finds that averaging over a rolling period of 15 years results in project efficiency values that are more consistent from year-to-year, reducing the impact of short-term trends. The Director finds that it is still

appropriate to remove project efficiencies greater or less than two standard deviations from the average.

The following is a table of efficiency values averaged over the most recent fifteen-year period of record.

Month	A&B	AFRD2	BID	Milner	Minidoka	NSCC	TFCC	Monthly Avg.
4	0.98	0.33	0.45	0.87	0.43	0.24	0.31	0.51
5	0.47	0.22	0.32	0.39	0.35	0.24	0.30	0.33
6	0.66	0.40	0.49	0.60	0.56	0.41	0.51	0.52
7	0.74	0.44	0.52	0.67	0.63	0.48	0.58	0.58
8	0.58	0.41	0.42	0.55	0.52	0.43	0.46	0.48
9	0.45	0.27	0.32	0.45	0.38	0.32	0.27	0.35
10	0.18	0.16	0.09	0.14	0.11	0.06	0.04	0.11
Season Avg.	0.58	0.32	0.37	0.52	0.43	0.31	0.35	

SWC Member Average Monthly Project Efficiencies from 2007-2021.[12]

ii. Crop Water Need

33. CWN is the volume of irrigation water required for crop growth within a SWC entity boundary, such that crop growth is not limited by water availability. CWN only applies to crops irrigated with surface water. CWN is the difference between the fully realizable consumptive use associated with crop growth, or ET, and effective precipitation (W_e) and is synonymous with the terms irrigation water requirement and precipitation deficit. Ex. 3024. For the purposes of the methodology, CWN is calculated as set forth below:

$$CWN = \sum_{i=1}^{n} (ET_i - W_e) A_i$$

Where,

CWN = crop water need
ET_i = consumptive use of specific crop type,
W_e = effective precipitation,
A_i = total irrigated area of specific crop type,
i = index variable representing the different specific crop types grown within the irrigation entity, and
n = upper bound of summation equal to the total number of different specific crop types grown within the irrigation entity.

[12] In the Fourth Methodology Order, this table summarized average E_p data for the period 2007 to 2014. This Fifth Methodology Order updates this table with average E_p data for the period 2007 to 2021.

iii. Evapotranspiration

34. ET can be estimated with theoretically based equations that calculate ET for an individual crop, necessitating crop distribution maps for each year. Ex. 3007A at 21, Figure 3, Tables 6-12; Ex. 3024 at 1-58; Ex. 8000, Vol. II at Chapter 9; Ex. 8000, Vol. IV, Appdx. AU.

35. At hearing, values of ET were estimated by the SWC from AgriMet, Ex. 8000, Vol. IV, Appdx. AU-1, and by the ground water users from ETIdaho, Ex. 3007A at 21; Ex. 3024 at 1-58. At this time, the Director finds that the use of AgriMet is more appropriate for determining ET than ETIdaho because AgriMet is available to all parties in real-time without the need for advanced programming. Accordingly, the methodology will rely on AgriMet derived ET values in the calculations of project efficiency, CWN, and RISD. In the future, with the development of additional enhancements, ETIdaho may become a more appropriate analytical tool for determining ET.[13]

36. CWN is derived by multiplying crop specific ET values, adjusted for estimated effective precipitation, by the total irrigated area of individual crop types, and summing for all crop types. The areas for individual crop types will be derived from published crop distributions from the United States Department of Agriculture's National Agricultural Statistics Service ("NASS"). Ex. 1005 at 1. NASS annually creates a crop-specific land cover digital dataset from satellite imagery and field checks. The dataset is called the Cropland Data Layer ("CDL"). Each year, the Department will calculate acreage by crop type for each SWC entity using NASS CDL data. In the future, the NASS data may not be the most accurate source of data. The Department prefers to rely on data from the current season if and when it becomes usable.

37. AgriMet ET and precipitation data are gathered at the Rupert and Twin Falls (Kimberly) stations. Both stations are in the vicinity of the SWC entities. A&B Irrigation District ("A&B"), Burley Irrigation District ("BID"), and Minidoka Irrigation District ("Minidoka") are nearest to the Rupert AgriMet station. ET data gathered at the Rupert station reasonably represents the climate conditions for A&B, BID, and Minidoka. American Falls Reservoir District No. 2 ("AFRD2"), Milner Irrigation District ("Milner"), North Side Canal Company ("NSCC"), and Twin Falls Canal Company ("TFCC") are nearest to the Twin Falls (Kimberly) AgriMet station. ET data gathered at the Twin Falls (Kimberly) station reasonably represents the climate conditions for AFRD2, Milner, NSCC, and TFCC. Ex. 8000, Vol. IV at AU-2, AU-8.

iv. Effective Precipitation

38. Effective precipitation ("W_e") is the amount of total precipitation held in the soil horizon available for crop root uptake. Effective precipitation will be estimated from total precipitation (W) employing the methodology presented in the USDA Technical Bulletin 1275. Ex. 8000, Vol. IV, Appdx. AU3, AU8. Total precipitation (W) data is published by the USBR as

[13] IDWR held a series of meetings in the winter of 2022-23 with the parties' technical consultants to discuss potential updates to the methodology order. During the meetings, IDWR discussed alternative methods of determining ET values, such as METRIC. However, the Director finds that the methods considered are not yet ready for incorporation into the administration of the SWC Delivery Call and will continue to rely on AgriMet ET data.

part of its Pacific Northwest Cooperative Agricultural Network, i.e. AgriMet.[14] Ex. 8000, Vol. IV, Appdx. AU3. W_e values derived from AgriMet based precipitation values are independent of crop type.

39. AgriMet precipitation (W) values are easy to understand and regularly used by the farming, water supply, and water management communities. Accordingly, the methodology will rely on AgriMet derived W values in the calculations of CWN and RISD.

40. As with ET data, AgriMet precipitation data are available from the Rupert and Twin Falls (Kimberly) stations. AgriMet data from the Rupert station reasonably represents climate conditions for A&B, BID, and Minidoka. AgriMet data from Twin Falls (Kimberly) reasonably represents climate conditions for AFRD2, Milner, NSCC, and TFCC. Ex. 8000, Vol. IV at AU-2, AU-8.

v. Summary of Reasonable In-Season Demand Calculation

41. At the start of the irrigation season, RISD is equal to the BD, or total season adjusted diversions for the BLY. When calculated in-season, RISD is calculated below.

$$RISD_{milestonex_x} = \sum_{j=1}^{m}\left(\frac{CWN_j}{E_{p,j}}\right) + \sum_{j=m+1}^{7} BD_j$$

Where:

$RISD_{milestone_x}$ = reasonable in season demand at specified evaluation milestones during the irrigation season,
CWN = crop water need for month j,
E_p = baseline project efficiency for month j,
BD = baseline demand for month j,
j = index variable, and
m = upper bound of summation, equal to the month calculation occurs, where April = 1, May =2, … October = 7.

42. April RISD Adjustment: In April, the calculated RISD, which is the quotient of CWN and Ep, can underestimate actual canal operation diversions. Under-estimation occurs when the actual CWN value for April is much smaller than the diversion of water into the canal system necessary to effectively operate the irrigation delivery system. Often, CWN in April is small due to precipitation, cool temperatures, and/or the immaturity of the crop. The diversion rate at the head gate necessary to push water into all laterals and field head gates throughout the delivery system often dwarfs the water necessary to strictly satisfy CWN. In addition, it is difficult for canal systems to be dynamically operated to match the frequent precipitation events in April, which also contributes to a diversion of water at the canal head gate that exceeds the diversion of water necessary to strictly satisfy CWN. To account for the conditions affecting the

[14] IDWR held a series of meetings in the winter of 2022-23 with the parties' technical consultants to discuss potential updates to the methodology order. During the meeting, IDWR discussed alternative methods to determine W values, such as PRISM. However, the Director finds that the methods considered are not yet ready for incorporation into the administration of the SWC Delivery Call and will continue to rely on AgriMet precipitation data.

usability of the calculated RISD value for April, the values may be adjusted for each individual irrigation delivery entity in the SWC as described below.

43. When the calculation of CWN/Ep results in a value for the month of April less than the average April diversion volume over a record of representative years in the recent past, the April RISD is set equal to the average April diversion volume. When the calculation of CWN/Ep results in a value greater than the average April diversion volume, the April RISD is equal to the calculated CWN/Ep volume.

44. October RISD Adjustment: In October, the calculated RISD, which is equal to the CWN divided by Ep, can both under-estimate and over-estimate actual canal operation diversions. The RISD may be underestimated when the actual CWN value for October is much smaller than the diversion of water into the canal system necessary to effectively operate the irrigation delivery system. The diversion rate at the head gate necessary to push water into all laterals and field head gates throughout the delivery system often dwarfs the water necessary to strictly satisfy CWN. In addition, it is difficult for canal systems to be dynamically operated to match the frequent precipitation events in October, which also contributes to a diversion of water at the canal head gate that exceeds the diversion of water necessary to strictly satisfy CWN. Furthermore, RISD may be underestimated in October when a farmer diverts water at the field head gate for farming practices other than strictly satisfying CWN. Examples of water diversion practices at the field head gate that sometimes occur in October include diverting water for soil salt leaching, diverting water to build up the soil moisture profile for the following irrigation season, and/or diverting water to wet-up bare soil to prevent wind-driven topsoil erosion.

45. Unlike the month of April, RISD can be over-estimated in October. RISD may be over-estimated in years when actual CWN in October is much greater than typical CWN over a record of representative years in the recent past due to low precipitation and/or warm temperatures. To account for the conditions affecting the usability of the RISD value calculated for October, the values may be adjusted for each individual irrigation delivery entity in the SWC as described below.

46. When the calculation of CWN/Ep results in a value for the month of October greater than the maximum October diversion volume from a record of recent representative years, or less than the minimum October diversion volume from the same record of recent representative years, the October RISD is set equal to the average October diversion volume over the same period of recent representative years. When the calculation of CWN/Ep results in a value between the maximum and minimum October diversion volumes from a record of recent representative years, the October RISD is equal to the calculated CWN/Ep volume.

D. Adjustment of Forecast Supply

47. As stated by the Hearing Officer, "There must be adjustments as conditions develop if any baseline supply concept is to be used." R. Vol. 37 at 7093. A prediction of the upcoming season's supply and demand is calculated at the beginning of the irrigation season and

adjusted at specified milestones during the irrigation season to address changes in water supply and demand conditions in response to actual climatic and water supply conditions.

i. April Forecast Supply

48. The FS is comprised of natural flow and stored water.

49. Typically, within the first week of April, the USBR and the USACE issue their Joint Forecast that predicts an unregulated inflow volume at the Heise Gage from April 1 to July 31 for the forthcoming year. The joint forecast ("Joint Forecast") issued by the United States Bureau of Reclamation ("USBR") and the United States Army Corp of Engineers ("USACE") for the period April 1 through July 31 "is generally as accurate a forecast as is possible using current data gathering and forecasting techniques." R. Vol. 8 at 1379, ¶ 98. Given current forecasting techniques, the earliest the Director can predict material injury "with reasonable certainty" is soon after the Joint Forecast is issued. R. Vol. 2 at 226. With data from 1990 through the irrigation year previous to the current year, a regression equation will be developed for each SWC member.[15] The regression equations for A&B and Milner will be developed by comparing the actual Heise natural flow to the natural flow diverted. *See e.g.* R. Vol. 8 at 1416-22. For AFRD2, BID, Minidoka, NSCC, and TFCC, multi-linear regression equations will be developed by comparing the actual Snake River near Heise natural flow and the flows at Box Canyon to the natural flow diverted. The regression equations will be used to predict the natural flow diverted for the upcoming irrigation season. *Id*. at 1380. The actual natural flow volume predicted in the Director's April FS for each SWC entity will be one standard error below the regression line, which underestimates the available supply. *Id*.; Tr. p. 65, lns. 6-25; p. 66, lns. 1-2. The purpose of the shift to one standard error below the regression line is to ensure senior water right holders do not bear the risk of under-prediction of supply. The forecasting techniques will be revised based on updated data and the forecasting techniques may be revised when improvements to the forecasting tools occur.

50. The storage allocation for each member of the SWC will be estimated by the Department following issuance of the Joint Forecast. The Department will forecast reservoir fill and storage allocation consistent with the methods established in the *Fifth Supplemental Order Amending Replacement Water Requirements Final 2006 & Estimated 2007.* R. Vol. 23 at 4294-97 as explained below. The Department will evaluate the current reservoir conditions and the current water supply outlook to determine a historical analogous year or years to predict reservoir fill. The Department may identify and use a combination of different analogous years to predict individual reservoir fill. Input variables for determining the individual storage water allocation for each SWC member are: (a) the analogous year's or years' total reservoir fill volume; (b) an estimated evaporation volume; and (c) the previous year's carryover volume. The FS (the combination of the forecast of natural flow supply and the storage allocation) for each SWC member will be determined by the Director shortly after the date of the Joint Forecast.

[15] IDWR held a series of meetings in the winter of 2022-23 with the parties' technical consultants to discuss potential updates to the methodology order. During the meetings, IDWR discussed updating the regression models used to forecast the SWC's water supplies in April. However, the Director finds that the current models still adequately forecast water supplies in April and will continue to rely on the existing regression models.

51. Any time prior to the Director's final determination of the April FS, if the Director can determine with certainty that any member of the SWC has diverted more natural flow than predicted, or has accrued more storage than predicted, the Director will revise his initial, projected shortfall determination.

ii. July Forecast Supply

52. Approximately halfway through the irrigation season, the FS will be adjusted. When adjusting the natural flow component of the FS, the Department's water rights accounting program will compute the year-to-date natural flow diverted by each member of the SWC. The natural flow diversion for the remainder of the irrigation season will be estimated based on the regression analyses.

53. The natural flow supplies for each SWC member are comprised of natural flow in the Snake River passing the near Blackfoot gage and gains that occur in the Snake River between the Blackfoot to Milner reach. Many different predictor variables were considered when developing the models used to predict the natural flow supplies for the remainder of the season, including those variables used in the April FS.[16] A step-wise statistical analysis was employed to help select the variables for each model. The following variables were selected to forecast water supplies halfway through the irrigation season: natural flow in the Snake River near Heise as reported by the U.S. Bureau of Reclamation; snow water equivalent (SWE) data at the Two Ocean Plateau SNOTEL site; Spring Creek discharge; and groundwater levels near American Falls Reservoir. The model predictors were optimized for each SWC member and are summarized in the sections below.

54. Linear regression equations for AFRD2, A&B, and Milner, will be developed by comparing the July 1 snow water equivalent (inches) at the Two Ocean Plateau SNOTEL site to the natural flow diversions. The regression equations for AFRD2, A&B, and Milner will be applied only in those years when the snow water equivalent at the Two Ocean Plateau SNOTEL site is greater than zero (0). Years when the snow water equivalent equals zero, the total natural flow prediction for the period July 1 to October 31 will be zero (0) AF.

55. Multiple linear regression equations for BID, Minidoka, and NSCC will be developed to predict natural flow diversions employing the following predictor variables: (1) Snake River near Heise natural flow (April – June), (2) March depth to water at well 05S 31E 27ABA1 and (3) the snow water equivalent at the Two Ocean Plateau SNOTEL site on June 15.

56. The multiple linear regression model for TFCC will be based on the following predictor variables: (1) Snake River near Heise natural flow (April – June), (2) Spring Creek total discharge (January – May) and (3) the snow water equivalent at the Two Ocean Plateau SNOTEL site on June 15.

[16] IDWR held a series of meetings in the winter of 2022-23 with the parties' technical consultants to discuss potential updates to the methodology order. IDWR discussed updating the regression models used to forecast the SWC's water supplies in July. However, the Director finds that the current models still adequately forecast water supplies in July and will continue to rely on the existing regression models.

57. When adjusting the storage component of the FS, the Department must consider whether stored water has been allocated. In normal to dry years, the reservoirs will typically have filled to their peak capacity for the season and the storage water will have been allocated. If the BOR and Water District 01 have allocated stored water to spaceholders, the Department will use the actual preliminary storage allocations to the SWC. If the BOR and Water District 01 have not yet allocated stored water to spaceholders, the Department will predict the storage allocations based on the storage allocations from an analogous year or years.

iii. Time of Need

58. The FS will again be adjusted shortly before the Time of Need. The Time of Need is established by predicting the day in which the remaining storage allocation will be equal to reasonable carryover. The Time of Need will not be earlier than the Day of Allocation.

59. When adjusting the natural flow component of the FS, the Department's water rights accounting program will compute the natural flow diverted by each member of the SWC as of the new forecast date. The natural flow diversion for the remainder of the irrigation season will be estimated based on a historical year with similar reach gains in the Blackfoot to Milner reach. The following is an example of estimating reach gains from an analysis of historical years. Reach gains for the years 2000 – 2003 and a portion of year 2004 are graphed below. Considering 2004 as an example of a current year and comparing 2004 to the hydrographs for 2000 – 2003, year 2003 has similar reach gains and is appropriately conservative. Therefore, the natural flow diverted in 2003 would be used to predict the natural flow diversions for the remainder of the 2004 season.

Example Reach Gain Analysis for 2004.

60. When adjusting the storage component of the FS, the Department will use the actual preliminary storage allocations to the SWC.

61. The adjusted FS is the sum of the year-to-date natural flow diversions, the predicted natural flow diversions for the remainder of the season, and the storage allocation.

E. Calculation of In-Season Demand Shortfall

62. The equation below determines the amount of predicted demand shortfall during the irrigation season.

$$IDS = FS - RISD$$

Where:

IDS = demand shortfall for specified evaluation points throughout the season,
FS = forecasted supply adjusted for specified evaluation point during the season, and
RISD = reasonable in-season demand from above.

63. The amount calculated represents the volume that junior ground water users with approved mitigation plans for delivery of water will be required to have available for delivery to members of the SWC found to be materially injured by the Director to avoid curtailment. The amounts will be calculated in April, at the middle of the season, and at the Time of Need.

III. Methodology for Determining Material Injury to Reasonable Carryover

64. Conjunctive Management ("CM") Rule 42.01.g states the following guidance for determining reasonable carryover: "In determining a reasonable amount of carry-over storage water, the Director shall consider average annual rate of fill of storage reservoirs and the average annual carry-over for prior comparable water conditions and the projected water supply for the system." Carryover shortfall will be determined following the completion of the irrigation season.

A. Projected Water Supply

65. CM Rule 42.01.g states that the Director "shall consider . . . the projected water supply for the system." Because it is not possible to adequately forecast the irrigation supply or demand for the following irrigation season at the end of the current irrigation season, the Director must estimate the carryover water needed in future dry years when demand exceeds supply, creating a need for carryover storage. The Director projected the water supply using typical dry years and subtracted it from a projected future demand to determine a projected carryover need.

66. The Heise natural flow is a predictive indicator of total water supply. For the years 2002 and 2004, the Heise natural flows were well below the long term average (1992-2021), but were not the lowest years on record.[17] The average of the 2002 and 2004 supply will be the projected supply, representing a typical dry year. The 2002 and 2004 supply is computed as follows:

- 2002 supply = natural flow diverted + new storage fill
- 2004 supply = natural flow diverted + new storage fill
- Projected supply = average of 2002 supply and 2004 supply

Carryover from previous years is not included in the 2002 and 2004 new storage fill because it was not new water supplied during the 2002 or 2004 irrigation year.

	2002 Natural Flow Diverted	2002 New Storage Fill	2002 Total Supply	2004 Natural Flow Diverted	2004 New Storage Fill	2004 Total Supply	Projected Supply (Average 02/04)
	----------Acre-Feet----------						
A&B	853	45,603	46,456	1	36,535	36,536	41,496
AFRD2	25,749	381,451	407,200	4,562	309,698	314,260	360,730
BID	89,886	174,454	264,340	102,706	152,387	255,093	259,716
Milner	5,058	43,430	48,488	1,027	35,175	36,202	42,345
Minidoka	143,937	256,602	400,539	141,460	229,574	371,034	385,787
NSCC	363,960	667,799	1,031,759	315,942	479,068	795,010	913,385
TFCC	851,970	186,233	1,038,203	881,345	150,218	1,031,563	1,034,883

SWC water supplies 2002, 2004, and 2002/2004 average (acre-feet).

67. Similar to projecting supply, the Director must also project demand. Because it is not possible to adequately forecast the irrigation demand for the following irrigation season at the end of the current irrigation season, the Director must project demand. R. Vol. 37 at 7109. The 2018 BLY will be the projected demand.

[17] The Fourth Methodology Order included data for the period 1991 to 2014. This Fifth Methodology Order updates this chart with data for the period 1992 to 2021.

68. The maximum projected carryover need is defined as the difference between a BLY demand and projected typical dry year supply. The following equation computes the maximum projected carryover need:

Maximum Projected Carryover Need = Projected Demand (2018 BLY) – Projected Supply (Average 02/04)

	Projected Demand (2018 BLY)	Projected Supply (average 02/04)	Maximum Projected Carryover Need
	----------Acre-Feet----------		
A&B	64,192	41,496	22,696
AFRD2	453,890	360,730	93,160
BID	262,211	259,716	2,495
Milner	58,417	42,345	16,072
Minidoka	354,851	385,787	0
NSCC	1,026,661	913,385	113,277
TFCC	1,121,717	1,034,883	86,834

SWC Projected Demand, Projected Supply and Maximum Projected Carryover Need (acre-feet).[18]

B. Average Annual Rate of Fill

69. CM Rule 42.01.g states that the Director "shall consider the average annual rate of fill of storage reservoirs . . . ." The average annual rate of fill of the storage reservoirs is the average of annual percentages of fill of each entity's reservoir space. The average annual reservoir storage fill is a benchmark that can be compared to projected carryover need. For purposes of the table below, any water contributed to the rental pool from the previous year was added to the next year's fill volume so that it does not artificially lower the percent fill. R. Vol. 37 at 7108. Water that is supplied to the rental pool lowers carryover and could impact the following year's fill. The percent fill does not include water deducted for reservoir evaporation.

[18] This Fifth Methodology Order updates this chart with the new baseline year and calculates new maximum projected carryover need values.

The annual percent fill of storage volume by SWC entity is shown below:

Year	A&B	AFRD2	BID	Milner	Minidoka	NSCC	TFCC
1992	96%	100%	98%	93%	75%	76%	86%
1993	100%	100%	100%	100%	100%	93%	92%
1994	100%	100%	100%	100%	99%	99%	99%
1995	100%	100%	100%	100%	100%	100%	100%
1996	100%	100%	100%	100%	100%	100%	100%
1997	100%	100%	100%	100%	100%	100%	100%
1998	100%	100%	100%	100%	100%	100%	100%
1999	100%	100%	100%	96%	98%	98%	99%
2000	100%	99%	99%	98%	100%	97%	97%
2001	100%	100%	100%	100%	100%	91%	87%
2002	41%	100%	100%	79%	92%	84%	88%
2003	43%	100%	99%	66%	92%	94%	99%
2004	34%	82%	97%	48%	94%	78%	63%
2005	58%	100%	100%	76%	98%	100%	100%
2006	98%	100%	99%	98%	100%	99%	99%
2007	89%	100%	97%	92%	94%	95%	97%
2008	100%	100%	100%	100%	100%	99%	100%
2009	100%	100%	100%	100%	100%	100%	100%
2010	100%	100%	100%	100%	100%	100%	100%
2011	100%	100%	100%	100%	100%	100%	100%
2012	88%	100%	97%	91%	94%	94%	96%
2013	80%	100%	97%	90%	90%	97%	100%

Annual Percent Fill of Storage Volume by Entity (1992-2021).[19]

[19] The Fourth Methodology Order included data from 1995 through 2014. This Fifth Methodology Order updates this chart with data from 1992 through 2021.

C. Average Annual Carryover

70. CM Rule 42.01.g states that the Director "shall consider the . . . average annual carry-over for prior comparable water conditions . . .." Actual carryover volumes are from annual storage reports published by Water District 1. Actual carryover from 1992 through 2021 are sorted into two categories – below average (dry) and above average (wet). The categories are based on Heise natural flow volumes from April through September.

The 1992 to 2021 average natural flow volume is 3,827 thousand acre-feet ("KAF").

Cat.	Year	Heise Apr–Sept (KAF)	A&B	AFRD2	BID	Milner	MID	NSCC	TFCC
			----------	----------	----------	Acre-Feet	----------	----------	----------
	2001	1,968	9,902	4,217	37,430	26,854	55,132	42,421	26,917
	1992	2,001	11,966	11,548	31,977	28,896	16,928	19,439	3,590
	1994	2,319	82,885	26,894	54,136	45,902	102,823	128,356	38,686

Actual Carryover Volumes by Entity, Sorted by Heise Natural Flow (1992-2021).[20]

[20] In the Fourth Methodology Order, this table summarized data for the period 1994 to 2014 and adjusted WD 01 carryover values to remove water received for mitigation or water rented by the SWC entity to augment their supplies. This Fifth Methodology Order updates this chart with data for the period 1992 to 2021 and uses raw

71. In considering the principles articulated in CM Rule 42.01.g, the Director will project reasonable carryover shortfalls for members of the SWC. The following table represents the 2018 BLY diversion volumes and total reservoir storage space by entity. By dividing the total reservoir space by the 2018 diversion volume, a metric is established that describes the total number of seasons the entity's reservoir space can supply water.

	A&B	AFRD2	BID	Milner	Minidoka	NSCC	TFCC
	----------Acre-Feet----------						
Projected Demand (2018 BLY)	64,192	453,890	262,211	58,417	354,851	1,026,661	1,121,717
Total Reservoir Space	137,626	393,550	226,487	90,591	366,554	859,898	245,930
Number of Seasons of Reservoir Space	2.1	0.9	0.9	1.6	1.0	0.8	0.2

Total Reservoir Space[21] in Comparison to Demand.[22]

D. Reasonable Carryover

i. A&B

72. A&B's reservoir space has the lowest average annual rate of fill with the highest variability in fill. *See* Finding of Fact 69. In dry years, the potential exists that A&B's actual carryover will be less than the maximum projected carryover need. *See* Finding of Fact 68 & 70. A&B has an approximate two-year water supply provided by its total available storage space. *See* Finding of Fact 71. Because of its lower rate of fill, it is likely A&B will experience carryover shortfalls in consecutive dry years. Based on the evaluation criteria in CM Rule 42.01.g, A&B's reasonable carryover should be the maximum projected carryover need of 22,700 AF. *See* Finding of Fact 78.

ii. AFRD2

73. AFRD2 has the highest and most consistent reservoir rate of fill of any member of the SWC. AFRD2's storage space fills 99% of the time and has a fill variability of 3%. As

carryover values reported by WD 01. Raw numbers were used because adjusted numbers reduced the SWC's potential entitlement to reasonable carryover.

[21] *See* R. Vol. 8 at 1373-74.

[22] This Fifth Methodology Order updates this chart with the new baseline year and calculates new number of seasons of reservoir space values.

shown in the Annual Percent Fill table in Finding of Fact 69 above, its space only failed to fill in 2004 (82%) and 2000 (99%). AFRD2 has a high likelihood of filling during multi-year droughts and after a dry year. *See* Finding of Fact 69. Therefore, any unfilled space in the fall will most likely fill. AFRD2 has an approximate one-year supply available in storage. *See* Finding of Fact 71. AFRD2's storage space only failed to fill in years when the natural flow volume at Heise was less than 3,100 KAF. In a dry year, AFRD2's historical carryover volume is often less than the maximum projected carryover need using the equation set forth in Finding of Fact 68 and 70. Based on the evaluation criteria for reasonable carryover in CM Rule 42.01.g, the reasonable carryover can be adjusted from the maximum projected carryover need without shifting the risk of shortage to the senior right holder. The historical average carryover of 16,700 AF in years when the natural flow volume at Heise was less than 3,100 KAF is the reasonable carryover for AFRD2. *See* Finding of Fact 78.

iii. BID & Minidoka

74. Historically, in dry years, BID's and Minidoka's carryover volumes have been well above the maximum projected carryover need and it is unlikely that they will have reasonable carryover shortfalls in the future. *See* Finding of Fact 68 & 70; *see also* R. Vol. 37 at 7105. Based on the evaluation criteria for reasonable carryover in CM Rule 42.01.g, the reasonable carryover can be adjusted downward from the maximum projected carryover need without shifting the risk of shortage to the senior right holder. The reasonable carryover for BID and Minidoka is 0 AF. *See* Finding of Fact 78; *see also* R. Vol. 37 at 7105.

iv. Milner

75. Similar to A&B, Milner's reservoir space has the second lowest average annual rate of fill of all entities and has a high degree of variability in fill. *See* Finding of Fact 69. In dry years, the potential exists that Milner's actual carryover will be less than the maximum projected carryover need. *See* Finding of Fact 68 & 70. Milner has an approximate one and one half water supply available in storage. *See* Finding of Fact 71. Because of its rate of fill, it is likely Milner will experience carryover shortfalls in consecutive dry years. Based on the evaluation criteria for reasonable carryover in CM Rule 42.01.g, the maximum projected carryover need of 16,100 AF is the reasonable carryover for Milner. *See* Finding of Fact 78.

v. NSCC

76. NSCC has a near-average annual rate of fill in comparison to all entities and an approximate one-year water supply available in storage. *See* Findings of Fact 69 & 71. In dry years, the potential exists that its maximum projected carryover need will be less than its actual carryover. *See* Finding of Fact 68 & 70. Based on the evaluation criteria in CM Rule 42.01.g, the reasonable carryover for NSCC is 113,300 AF. *See* Finding of Fact 77.

vi. TFCC

77. TFCC has a near average annual rate of fill in comparison to all entities, but only 20% of a single year's water supply is available in storage. TFCC's storage space fills 97% of

the time and has a fill variability of 8%. *See* Findings of Fact 69 & 71. In dry years, the potential exists that its maximum projected carryover need will be less than its actual carryover. *See* Finding of Fact 68 & 70. Based on the evaluation of the criteria in CM Rule 42.01.g, the reasonable carryover can be adjusted from the maximum projected carryover need without shifting the risk of shortage to the senior right holder. The historical average carryover in dry years of 37,400 AF is the reasonable carryover for TFCC. *See* Finding of Fact 78.

78. Reasonable carryover values for the SWC members are as follows:

	Reasonable Carryover (Acre-Feet)
A&B	22,700
AFRD2	16,700
BID	0
Milner	16,100
Minidoka	0
NSCC	113,300
TFCC	37,400

E. Reasonable Carryover Shortfall

79. Reasonable carryover shortfall is the numerical difference between reasonable carryover and actual carryover, calculated at the conclusion of the irrigation season. Actual carryover is defined as the storage allocation minus the total storage use plus or minus any adjustments. Examples of adjustments include SWC water placed in the rental pool and SWC private leases. Adjustments are unique to each irrigation season and will be evaluated each year. Any storage water deliveries to entities other than the SWC for purposes unrelated to the original right will be adjusted so that the water is not included as a part of the SWC carryover volume. Water that is purchased or leased by an SWC member may become part of the carryover shortfall obligation. *See e.g.* R. Vol. 38 at 7201, n. 11 (Eighth Supplemental Order). Conversely, actual carryover must be adjusted to assure that water supplied by a SWC member to private leases or to the rental pool will not increase the reasonable carryover shortfall obligation to the same SWC member.

80. Reasonable carryover shortfall is calculated as follows:

Reasonable Carryover Shortfall = Actual Carryover – Reasonable Carryover

F. Determination of Curtailment Date

81. The Eastern Snake Plain Aquifer Model ("ESPAM") is the best scientific tool available to simulate aquifer and Snake River responses to stresses applied to the aquifer, such as ground water pumping from a well. Curtailment of junior ground water pumpers in response to the SWC Delivery Call would result in a reduction in the withdrawal of groundwater and a corresponding reduction in aquifer stress. ESPAM simulates the effects of the reduction in

aquifer stress and calculates predicted increases in aquifer discharge to the Snake River resulting from the curtailment of ground water pumping from the ESPA.

82. ESPAM simulations can be either steady-state or transient.

83. Merriam-Webster's Dictionary defines steady-state as "a state or condition of a system or process … that does not change in time." *Steady state*, Merriam-Webster.com, https://www.merriam-webster.com/dictionary/steady-state (April 19, 2023). A steady-state ESPAM simulation can only model increases in aquifer discharge to the Snake River resulting from continuous curtailments of an identical magnitude and location until the impacts of curtailment are fully realized. For example, a steady-state analysis of the curtailment of 1,000 acres, assumes that irrigation of the same 1,000 acres is curtailed every year at the same rate of consumptive use, until the impacts of that curtailment reach a steady state, or no longer change from year to year.

84. Steady-state analysis does not calculate the time to reach steady-state conditions nor describe the seasonal timing of the impacts. For the benefits of curtailment predicted by steady-state analysis to be realized by the river, the curtailment must occur continuously until steady-state is achieved. The assumption of continuous curtailment does not reflect reality in the SWC Delivery Call. Curtailments ordered as prescribed in the methodology are neither continuous nor long-term. Irrigation with ground water does not occur at a constant rate throughout the year nor from year to year. It is important to predict what benefits to the river are realized during the irrigation season in which injury has been determined. A steady-state ESPAM simulation cannot predict what benefits are realized during the irrigation season. In contrast, a transient ESPAM simulation will predict the timing of changes in river reach gains.

85. ESPAM was calibrated using one-month stress periods and can simulate a single (or partial) irrigation season of curtailment and predict the resulting increase in aquifer discharge to the Snake River during the same irrigation season using a transient simulation. In the context of this proceeding, the transient approach identifies the junior ground water rights that must be curtailed to produce increases in Snake River flows sufficient to offset material injury in the current irrigation season.

86. Only 9% to 15% of the steady state response is predicted to accrue to the near Blackfoot to Minidoka reach between May 1 and September 30 of the same year.[23] Fifty percent of the steady-state response is predicted to accrue at the near Blackfoot to Minidoka reach within approximately four years. Ninety percent of the steady-state response is predicted to accrue at the near Blackfoot to Minidoka reach within approximately 24 years.

87. A curtailment to a priority date calculated by the steady state analysis method used in the Fourth Methodology Order will only offset 9% to 15% of the predicted IDS. In contrast, curtailment to a priority date calculated with a transient simulation of a single season curtailment will offset the full predicted IDS unless the shortfall exceeds the accruals to the near

[23] The near Blackfoot to Minidoka reach is the reach of the Snake River from which the SWC diverts.

Blackfoot to Minidoka reach by the end of the irrigation season with curtailment of all junior ground water rights.

88. Steady-state simulations are appropriate for evaluating the average annual impact of aquifer stresses that have been, or will be, applied for decades (i.e., ground water pumping year after year, or continuous curtailment to the same date every year). The steady-state simulation of continuous curtailment applied in the Fourth Amended Methodology Order does not simulate the short-term curtailments prescribed in the methodology. The methodology prescribes curtailment only in years with a predicted IDS or carryover shortfall and prescribes the determination of a curtailment priority date that varies with the magnitude of the predicted shortfall.

89. Transient simulations are necessary to evaluate the impacts of aquifer stresses applied for short periods of time (i.e. short-term curtailments with varying priority dates). Transient simulations are necessary to simulate the short-term curtailments prescribed in the methodology.

CONCLUSIONS OF LAW

1. This order contains the methodology by which the Director will determine material injury to RISD and reasonable carryover to members of the SWC.

2. "The agency's experience, technical competence, and specialized knowledge may be utilized in the evaluation of the evidence." Idaho Code § 67-5251(5); IDAPA 37.01.01.600.

3. Idaho Code § 42-602 states that, "The director of the department of water resources shall have discretion and control of the distribution of water from all natural sources . . . . The director of the department of water resources shall distribute water . . . in accordance with the prior appropriation doctrine." According to the Hearing Officer, "It is clear that the Legislature did not intend to grant the Director broad powers to do whatever the Director might think right. However, it is clear also that the Legislature [in Idaho Code § 42-602] did not intend to sum up water law in a single sentence of the Director's authority." R. Vol. 37 at 7085. "Given the nature of the decisions which must be made in determining how to respond to a delivery call, there must be some exercise of discretion by the Director." *American Falls Res. Dist. No. 2 v. Idaho Dept. Water Resources*, 143 Idaho 862, 875, 154 P.3d 433, 446 (2007).

4. "The prior appropriation doctrine is comprised of two bedrock principles—that the first appropriator in time is the first in right and that water must be placed to a beneficial use." *In Matter of Distribution of Water to Various Water Rights Held by or for the Benefit of A & B Irrigation Dist.*, 155 Idaho 640, 650, 315 P.3d 828, 838 (2012). "The concept that beneficial use acts as a measure and limit upon the extent of a water right is a consistent theme in Idaho water law." *Id.*; *American Falls*, 143 Idaho at 879, 154 P.3d at 450 (stating that while an appropriation for a beneficial use is "a valuable right entitled to protection . . . . Nevertheless, that property right is still subject to other requirements of the prior appropriation doctrine."); *Idaho Ground Water Assoc. v. Idaho Dep't of Water Res.*, 160 Idaho 119, 131, 369 P.3d 897, 909

(2016) (explaining the "policy of beneficial use" serves as a "limit on the prior appropriation doctrine.").

5. "Concurrent with the right to use water in Idaho 'first in time,' is the obligation to put that water to beneficial use." *American Falls*, 143 Idaho at 880, 154 P.3d at 451; *see In re Distribution of Water to Various Water Rights Held by or for the Ben. of A&B Irr. Dist.*, 155 Idaho at 652, 315 P.3d at 840 (quoting *American Falls*, 143 Idaho at 876, 154 P.3d at 447) (referring to "'the constitutional requirement that priority over water be extended only to those using the water'"). "'It is the settled law of this state that no person can, by virtue of a prior appropriation, claim or hold more water than is necessary for the purpose of the appropriation, and the amount of water necessary for the purpose of irrigation of the lands in question and the condition of the land to be irrigated should be taken into account.'" *In re Distribution of Water to Various Water Rights Held by or for the Ben. of A&B Irr. Dist.*, 155 Idaho at 650, 315 P.3d at 838 (quoting *Washington State Sugar v. Goodrich*, 27 Idaho 26, 44, 147 P. 1073, 1079 (1915)).

6. "[T]he policy of securing the maximum use and benefit, and least wasteful use of Idaho's water resources, has long been the policy in Idaho." *Idaho Ground Water Assoc.*, 160 Idaho at 131, 369 P.3d at 909 (citing *Clear Springs Foods, Inc. v. Spackman*, 150 Idaho 790, 808, 252 P.3d 71, 89 (2011)). The Idaho Constitution enunciates a policy of promoting "optimum development of water resources in the public interest." Idaho Const. Art. XV, § 7; *Baker v. Ore-Ida Foods, Inc.,* 95 Idaho 575, 584, 513 P.2d 627, 636 (1973). "There is no difference between securing the maximum use and benefit and least wasteful use of this State's water resources and the optimum development of water resources in the public interest. Likewise, there is no material difference between 'full economic development' and the 'optimum development of water resources in the public interest.' They are two sides of the same coin. Full economic development is the result of the optimum development of water resources in the public interest." *Clear Springs*, 150 Idaho at 809, 252 P.3d at 90. "The policy of securing the maximum use and benefit, and least wasteful use, of the State's water resources applies to both surface and ground waters, and it requires that they be managed conjunctively." *Id.*

7. "Conjunctive administration 'requires knowledge by the [Department] of the relative priorities of the ground and surface water rights, how the various ground and surface water sources are interconnected, and how, when, where and to what extent the diversion and use of water from one source impacts the water flows in that source and other sources.' . . . . That is precisely the reason for the CM Rules and the need for analysis and administration by the Director." *American Falls,* 143 Idaho at 877, 154 P.3d at 448.

8. The CM Rules incorporate all principles of the prior appropriation doctrine as established by Idaho law. *American Falls*, 143 Idaho at 873, 154 P.3d at 444; CM Rule 20.02, 10.12.

9. While the presumption under Idaho law is that an appropriator is entitled to his decreed water right and the CM Rules may not be applied to require a senior appropriator to demonstrate an entitlement to the water in the first place, there may be post-adjudication factors relevant to the determination of how much water is actually needed in responding to a delivery call. *American Falls*, 143 Idaho at 877-78, 154 P.3d at 448-49. Under the CM Rules and Idaho law, the Director has the "authority and responsibility to investigate claims when delivery calls

are made," and the "authority to evaluate the issue of beneficial use in the administration context." *In re Distribution of Water to Various Water Rights Held by or for the Ben. of A&B Irr. Dist.*, 155 Idaho at 652, 315 P.3d at 840. As the Idaho Supreme Court stated, "'[w]hile the prior appropriation doctrine certainly gives pre-eminent rights to those who put water to beneficial use first in time, this is not an absolute rule without exception . . . the Idaho Constitution and statutes do not permit waste and require water to be put to beneficial use or be lost.'" *Idaho Ground Water Assoc.*, 160 Idaho at 131, 369 P.3d at 909 (quoting *American Falls*, 143 Idaho at 880, 154 P.3d at 433). "[T]he Director must have some discretion to balance these countervailing considerations in a delivery call." *Id*. "'If this Court were to rule the Director lacks the power in a delivery call to evaluate whether the senior is putting the water to beneficial use, we would be ignoring the constitutional requirement that priority over water be extended only to those using the water.'" *In re Distribution of Water to Various Water Rights Held by or for the Ben. of A&B Irr. Dist.*, 155 Idaho at 652, 315 P.3d at 840 (quoting *American Falls*, 143 Idaho at 876, 154 P.3d at 447).

10. In responding to a delivery call under the CM Rules, the Director "may employ a baseline methodology as a starting point for considering material injury," provided the baseline methodology otherwise comports with the prior appropriation doctrine as established by Idaho law. *In re Distribution of Water to Various Water Rights Held by or for the Ben. of A&B Irr. Dist.*, 155 Idaho at 653, 315 P.3d at 841; *see Methodology Remand Order* at 17.

11. Once the Director determines "that material injury is occurring or will occur," junior appropriators subject to the delivery call bear "the burden of proving that the call would be futile or to challenge, in some other constitutionally permissible way, the senior's call." *American Falls*, 143 Idaho at 878, 154 P.3d at 449; *Methodology Remand Order* at 31. Junior appropriators have the burden of proving by clear and convincing evidence that the delivery call is futile or otherwise unfounded. *In re Distribution of Water to Various Water Rights Held by or for the Ben. of A&B Irr. Dist.*, 155 Idaho at 653, 315 P.3d at 841.

12. "This case illustrates the tension between the first in time and beneficial use aspects of the prior appropriation doctrine." *In re Distribution of Water to Various Water Rights Held by or for the Ben. of A&B Irr. Dist.*, 155 Idaho at 650, 315 P.3d at 838. The Idaho Supreme Court has in this case "recognized the critical role of the Director in managing the water resources to accommodate both first in time and beneficial use aspects: 'Somewhere between the absolute right to use a decreed water right and an obligation not to waste it and to protect the public's interest in this valuable commodity, lies an area for the exercise of discretion by the Director.'" *Id.* at 651, 315 P.3d at 839 (quoting *American Falls*, 143 Idaho at 880, 154 P.3d at 451). Thus, in this case the Director may use "a baseline methodology, both as a starting point for consideration of the Coalition's call and in determining the issue of material injury." *Id.* at 650-51, 315 P.3d at 838-39. However, "[i]f changing conditions establish that material injury is greater than originally determined pursuant to the baseline analysis, then adjustments to the mitigation obligation of the juniors must be made when the Director undertakes his mid-season calculations." *Methodology Remand Order* at 18.

13. In the context of conjunctive administration, the Director's methodology for projecting material injury does not impose an obligation upon members of the SWC to reprove

their water rights. To the extent water is available, members of the SWC are authorized to divert and store water in accordance with the terms of their licenses or decrees. Nothing established herein reduces that authorization. The question that the CM Rules require the Director to answer in this proceeding is, when water is not available to fill the water rights of the SWC, how much water is reasonably necessary for the SWC to accomplish the beneficial purpose of raising crops; because what is needed to irrigate crops may be less than the decreed or licensed quantities. *American Falls*, 143 Idaho at 880, 154 P.3d at 451; *see In re Distribution of Water to Various Water Rights Held by or for the Ben. of A&B Irr. Dist.*, 155 Idaho at 650, 315 P.3d at 838 (quoting *Washington State Sugar*, 27 Idaho at 44, 147 P. at 1079) ("'[i]t is the settled law of this state that no person can, by virtue of a prior appropriation, claim or hold more water than is necessary for the purpose of the appropriation"). Again, "[t]he concept that beneficial use acts as a measure and limit upon the extent of a water right is a consistent theme in Idaho water law." *Id.*

14. Holders of senior-priority water rights may receive less than their licensed or decreed quantities and not suffer material injury within the meaning of the CM Rules. As a result, in-season demand should be viewed in light of reasonableness and optimum development of water resources in the public interest. CM Rules 20 and 42; *American Falls*, 143 Idaho at 876-80, 154 P.3d at 447-51; *In re Distribution of Water to Various Water Rights Held by or for the Ben. of A&B Irr. Dist.*, 155 Idaho at 650-652, 315 P.3d at 838-40.

15. Here, the Director has established a methodology for determining material injury to members of the SWC. The methodology predicts material injury to RISD by taking the difference between RISD and the FS. The years 2000 through 2021 were analyzed to select the BLY because the period of years captured current irrigation practices in a dry climate. Based upon evaluation of the record, members of the SWC were exercising more reasonable efficiencies during this time period than during the 1990s when supplies were more plentiful. During periods of drought when junior ground water users are subject to curtailment, members of the SWC should exercise reasonable efficiencies to promote the optimum utilization of the State's water resources. CM Rules 20 and 42; *American Falls,* 143 Idaho at 876-80, 154 P.3d at 447-51; *Clear Springs*, 150 Idaho at 807-10; 252 P.3d at 88-91; *In re Distribution of Water to Various Water Rights Held by or for the Ben. of A&B Irr. Dist.*, 155 Idaho at 650-652, 315 P.3d at 838-40.

16. At this time, with the recognition that the methodology is subject to adjustment and refinement, RISD will be equal to the historic demands associated with the BLY (2018) and will be corrected during the season to account for variations in climate and water supply between the BLY and actual conditions.

17. Recognizing that climate and surface water supplies (natural flow and storage) are inherently variable, the Director's predictions of material injury to RISD and reasonable carryover are based upon the best available information and the best available science, in conjunction with the Director's professional judgment as the manager of the State's water resources. Recognizing his ongoing duty to administer the State's water resources, the Director should use available data, and consider new analytical methods or modeling concepts, to evaluate the methodology. As more data is gathered and analyzed, the Director will continue to

review and refine the process of predicting and evaluating material injury. The methodology will continue to be adjusted if the data supports a change.

18. If the Director predicts that the SWC will be materially injured because of a demand shortfall prediction, either in the preseason or in the midseason, the demand shortfall represents a mitigation obligation that must be borne by junior ground water users. If mitigation water in the amount of the projected RISD shortfall cannot be secured or optioned by junior ground water users to the satisfaction of the Director, the Director will curtail junior ground water users to make up any deficit. *See* Order on Pet. for Jud. Rev., at 19, *A&B Irrigation District v. Idaho Dairymen's Association, Inc.*, No. 2008-0000551 (Gooding Cnty. Dist. Ct. Idaho July 24, 2009),

19. In previous years, the Director used steady-state modeling when determining the curtailment priority date. The Department now has multiple years of experience with the methodology to better understand the impact of applying steady-state modeling versus transient modeling to determine a curtailment priority date that would supply adequate water to the senior water right holders. While the first version of the ESPA groundwater flow model was not calibrated at a time-scale that supported in-season transient modeling, the current version was calibrated using monthly stress periods and half-month time steps, a refinement that facilitates in-season transient modeling for calculating the response to curtailment of groundwater use. As part of the Director's ongoing obligation to evaluate the methodology, the Director must evaluate whether the use of steady-state continues to be supportable.

20. In surface water administration, uses by holders of junior priority surface water rights are curtailed until the senior surface water rights are fully satisfied, absent a futile call and if the senior surface water users need the water to accomplish a beneficial use. In other words, under surface water administration, junior surface water rights are generally curtailed unless the senior gets water in the quantity and at the time and place required.

21. Rule 43 of the CM Rules mandates that when the Director evaluates a mitigation plan, the mitigation plan must ensure that water is delivered to holders of senior priority surface water rights in both the quantity and at the time and place required by the senior. In considering a proposed mitigation plan pursuant to Rule 43, the Director must evaluate:

> **b.** Whether the mitigation plan will provide replacement water, *at the time and place required by the senior-priority water right*, sufficient to offset the depletive effect of ground water withdrawal on the water available in the surface or ground water source *at such time and place as necessary* to satisfy the rights of diversion from the surface or ground water source. Consideration will be given to the history and seasonal availability of water for diversion so as not to require replacement water at times when the surface right historically has not received a full supply, such as during annual low-flow periods and extended drought periods.
> **c.** Whether the mitigation plan provides replacement water supplies or other appropriate compensation to the senior-priority water right *when needed during a time of shortage* even if the effect of pumping is spread over many years and will continue for years after pumping is curtailed. A mitigation plan may allow for

> multi-season accounting of ground water withdrawals and provide for replacement water to take advantage of variability in seasonal water supply. The mitigation plan must include contingency provisions to assure protection of the senior-priority right in the event the mitigation water source becomes unavailable.

IDAPA 37.01.03.11.043.b-c (emphasis added). In other words, there is an assumption that senior water right holders calling for delivery of water under the CM Rules will receive, by curtailment or by mitigation, "replacement water at the time and place required by the senior-priority water right, sufficient to offset the depletive effect of ground water withdrawal . . . ." Only in a mitigation plan can "multi-season accounting of ground water withdrawals" be employed, and even then, the plan must "assure protection of the senior-priority right in the event the mitigation water source becomes unavailable."

22. The Director has an obligation to address a mitigation deficiency in the year it occurs. Mem. Decision & Order on Pet. for Jud. Rev., at 10, *Rangen, Inc. v. Idaho Dep't of Water Res.*, No. CV-2014-2446 (Twin Falls Cnty. Dist. Ct. Idaho Dec. 3, 2014); Mem. Decision & Order, at 8–9, *Rangen, Inc. v. Idaho Dep't of Water Res.*, No. CV-2014-4970 (Twin Falls Cnty. Dist. Ct. Idaho June 1, 2015).

23. As described in Finding of Fact 87, curtailment to a priority date calculated by the steady state analysis method used in the Fourth Methodology Order will only offset 9% to 15% of the predicted IDS. In contrast, curtailment to a priority date calculated with a transient simulation of a single season curtailment will offset the *full* predicted IDS unless the shortfall exceeds the accruals to the near Blackfoot to Minidoka reach by the end of the irrigation season with curtailment of all junior ground water rights. This methodology order depends on an annual evaluation of material injury and should also employ curtailment and or mitigation that supplies replacement water at the time and place required by the senior-priority water right in a quantity sufficient to offset the depletive effect of ground water withdrawal and to assure protection of the senior-priority right. Curtailment dates, periodically determined at time of recalculating in-season demand shortfall (IDS), should be calculated by a transient model simulation that will return the full quantity of water to the senior priority rights at the time and place required.

24. As described in Conclusion of Law 18, junior ground water users with approved mitigation plans to deliver storage water as mitigation must, to the satisfaction of the Director, secure or option mitigation water to avoid curtailment. By requiring that junior ground water users secure mitigation water or have options to acquire water in place during the season of need, the Director ensures that the SWC does not carry the risk of shortage to their supply. By not requiring junior ground water users to deliver or assign mitigation water until the Time of Need, the Director ensures that junior ground water users supply only the amount of mitigation water necessary to satisfy the RISD. All approved methods of mitigation shall be considered in the Director's review of projected RISD shortfall.

25. Unless there is reasonable certainty that junior ground water users can secure the predicted volume of water and provide that water at the Time of Need, the protection afforded to the senior water right holders is compromised. The risk of shortage is then impermissibly shouldered by the SWC. Members of the SWC should have certainty entering the irrigation

season and at midseason that mitigation water will be delivered or assigned at the Time of Need, or curtailment of junior ground water rights will be ordered.

26. Because climate and the supply that the SWC appropriated (natural flow and storage) are inherently variable, the Director cannot and should not insulate the SWC against all shortages. The Director can, however, protect the SWC against reasonably predicted shortages to RISD.

27. Currently, the USBR and USACE's Joint Forecast is an indispensable predictive tool at the Director's disposal for predicting material injury to RISD. Given current forecasting techniques, the earliest the Director can predict material injury to RISD with reasonable certainty is soon after the Joint Forecast is issued in early April. The pre-irrigation season supply forecast for A&B and Milner can be predicted solely from the Joint Forecast. To improve the accuracy of prediction, the pre-irrigation season supply forecast for AFRD2, BID, Minidoka, NSCC, and TFCC will currently be predicted from both the Joint Forecast and from flow data at Box Canyon.[24]

28. By shifting the April Forecast Supply prediction curve down one standard error of estimate, the Director purposely underestimates the water supply that is predicted. The Director further guards against RISD shortage by using the 2018 BLY, which has above average diversions, above average ET, below average in-season precipitation, and above average growing degree days. The 2018 BLY represents a year in which water supply did not limit diversions. The Director's prediction of material injury to RISD is purposely conservative. While it may ultimately be determined after final accounting that less mitigation water was owed than was provided, this is an appropriate burden for junior appropriators to carry. Idaho Cost. Art. XV, § 3; Idaho Code § 42-106. Shifting the prediction curve down one standard error of estimate and adoption of a BLY that uses above average diversions, above average temperatures and ET and below average precipitation is necessary to protect senior rights if the Director administers to an amount less than the full decreed quantity of the SWC's rights. *Methodology Remand Order* at 33, 35.

29. The Director will review, at the end of the season, the volume and efficiencies of application of surface water, the amount of mitigation water provided by junior ground water users, and may, in the exercise of his professional judgment, readjust the reasonable carryover shortfalls to reflect these considerations.

30. "Storage water is water held in a reservoir and is intended to assist the holder of the water right in meeting their decreed needs." *American Falls*, 143 Idaho at 878, 154 P.3d at 449. "Carryover is the unused water in a reservoir at the end of the irrigation year which is retained or stored for future use in years of drought or low-water." *Id.* Under Idaho Code, "[o]ne may acquire storage water rights and receive a vested priority date and quantity, just as with any other water right," but "[t]here is no statutory provision for obtaining a decreed right to 'carryover' water." *Id.* Rather, carryover is a "component of the storage right." Order on Pet. for Jud. Rev., at 20, *A&B Irrigation District v. Idaho Dairymen's Association, Inc.*, No. 2008-

[24] The method for predicting the natural flow supply may be subject change based upon improved predictive models.

0000551 (Gooding Cnty. Dist. Ct. Idaho July 24, 2009). Storage carryover is "permissible . . . absent abuse." *American Falls*, 143 Idaho at 880, 154 P.3d at 451.

31. The storage reservoirs implicated in this proceeding were intended to provide supplemental supplies of water "to create a buffer against the uncertainty of the weather." *Opinion Constituting Findings of Fact, Conclusions of Law and Recommendation* (April 29, 2008) at 6. "The history of the development of the reservoir system, most recently Palisades, makes it clear that storage of water was a primary purpose to prevent disaster during periods of shortage as have been experienced in the recent past." *Id*. at 60. The purpose of carryover also is "insurance against the risk of future shortage." Order on Pet. for Jud. Rev., at 20, *A&B Irrigation District v. Idaho Dairymen's Association, Inc.*, No. 2008-0000551 (Gooding Cnty. Dist. Ct. Idaho July 24, 2009).

32. CM Rule 42.01 sets forth factors the Director "may consider in determining whether the holders of water rights are suffering material injury and using water efficiently and without waste." CM Rule 42.01 does not limit the Director's determination of reasonable carryover to consideration of the factors enumerated in CM Rule 42.01g, but only requires that the Director consider those enumerated factors. One such factor is "[t]he extent to which the requirements of the holder of a senior priority water right could be met with the user's existing facilities and water supplies." CM Rule 42.01g. This factor is qualified, however, by the provision that "the holder of a surface water storage right shall be entitled to maintain a reasonable amount of carry-over storage to assure water supplies for future dry years." CM Rule 42.01g. Thus, CM Rule 42.01g does not require water right holders to exhaust their storage water supplies prior to making a delivery call under the CM Rules. This is consistent with the purposes of the storage reservoirs and the carryover components of the storage water rights.

33. In considering CM Rule 42.01g in *American Falls*, the Idaho Supreme Court framed the SWC's challenge to the "reasonable carryover" provision as presenting the question of whether the holders of storage water rights are "entitled to insist on all available water to carryover for future years in order to assure that their full storage water is met (regardless of need)," *American Falls,* 143 Idaho at 879, 154 P.3d at 450, and answered this question in the negative:

> At oral argument, one of the irrigation district attorneys candidly admitted that their position was that they should be permitted to fill their entire storage water right, regardless of whether there was any indication that it was necessary to fulfill current or future needs and even though the irrigation districts routinely sell or lease the water for uses unrelated to the original rights. This is simply not the law of Idaho. While the prior appropriation doctrine certainly gives pre-eminent rights to those who put water to beneficial use first in time, this is not an absolute rule without exception. As previously discussed, the Idaho Constitution and statutes do not permit waste and require water to be put to beneficial use or be lost. Supra, paragraph 11.

Id. at 880, 154 P.3d at 451.

34. As discussed in the Findings of Fact, reasonable carryover is determined by projecting the water supply for the system. This is accomplished by projecting the 2002/2004 natural flow and average annual storage fill and the 2018 demand. Next, the Director examines the average annual rate of fill of each SWC entity's reservoir space to determine each entity's relative probability of fill. Finally, the Director examines the average annual carryover for prior comparable water conditions by reviewing Heise natural flow.

35. On or before November 30, the Department will issue estimates of actual carryover and reasonable carryover shortfall volumes for all members of the SWC. These estimates will establish the obligation of junior ground water users in providing water to the SWC for reasonable carryover shortfall. Fourteen (14) days following the issuance by the Department of reasonable carryover short fall obligations, junior ground water users will be required to establish, to the satisfaction of the Director, their ability to supply a volume of storage water or to conduct other approved mitigation activities that will provide water to the injured members of the SWC equal to the reasonable carryover shortfall for all injured members of the SWC. If junior ground water users cannot provide this information, the Director will issue an order curtailing junior ground water rights.

36. Recognizing that reservoir space held by members of the SWC may fill, and to prevent the waste of water, junior ground water users are not required to deliver or assign the volume of reasonable carryover until after the Day of Allocation (defined in footnote 27, *infra*). Junior ground water users are obligated to hold the secured or optioned mitigation water until reservoir space held by the SWC fills. If the reservoir space does not fill, junior ground water right holders must deliver or assign the secured or optioned mitigation water to the senior water right holders up to the amount of storage space that did not fill.

ORDER

Consistent with the forgoing, the Director HEREBY ORDERS that, for purposes of determining material injury to RISD and reasonable carryover, the following steps will be taken:

1. Step 1: By April 1, members of the SWC will submit electronic shape files to the Department delineating the total anticipated irrigated acres for the upcoming year within their water delivery boundary or confirm in writing that the existing electronic shape file submitted by SWC has not varied by more than five percent. Department staff will review submitted shapefiles and modify them as necessary to ensure that: (1) the total acreage count does not exceed the decreed number of acres; (2) all of the irrigated land is located within the decreed place of use; and (3) acres are not counted more than once due to overlapping polygons within a shape file or between shape files submitted by different SWC members. Because the SWC members can best determine the irrigated acres within their service area, the SWC should be responsible for submitting the information to the Department. If this information is not timely submitted, the Department will determine the total irrigated acres based upon past cropping patterns and current satellite and/or aerial imagery. If a SWC member fails or refuses to identify the number of irrigated acres within its service area by April 1, the Department will be cautious about recognizing acres as being irrigated if there is uncertainty about whether the acres are or will be irrigated during the upcoming irrigation season. The Department will electronically post

electronic shape files for each member of the SWC for the current water year for review by the parties. In determining the total irrigated acreage, the Department may account for supplemental ground water use. The Department currently does not have sufficient information to accurately determine the contribution of supplemental ground water to lands irrigated with surface water by the SWC. If and when reliable data is available to the Department, the methodology will be amended to account for the supplemental ground water use.

2. If the acreage count is under reported by more than five percent of the irrigated acreage limit of the water right, then the Department will assess the impact of this reduction in use of the water right on any mitigation requirement.

3. Step 2: Typically within the first two weeks of April, the USBR and USACE issue their Joint Forecast that predicts an unregulated inflow volume at the Heise Gage for the period April 1 through July 31. Within fourteen (14) days after issuance of the Joint Forecast, the Director will issue a final order predicting the April FS for the water year for each SWC entity. The Director will compare the April FS for each SWC entity to the BD for each SWC entity to determine if an in-season demand shortfall ("IDS") is anticipated for the upcoming irrigation season. The April FS for each SWC entity is the sum of the forecasted natural flow supply and the forecasted storage allocation for each SWC entity. The forecasted natural flow supply will be computed with regression algorithms. The forecasted storage allocation will be determined by comparing storage accruals in an analogous year(s). A transient ESPAM simulation will be run to calculate the curtailment priority date predicted to produce a volume of water equal to the IDS in the near Blackfoot to Minidoka reach between May 1 and September 30 of the current year. Curtailment will be simulated within the area of common ground water supply as described by CM Rule 50.01.

4. Step 3: By May 1, or within fourteen (14) days from issuance of the final order predicting the April FS, whichever is later in time, junior ground water users with approved mitigation plans for delivery of water must secure, to the satisfaction of the Director, a volume of water equal to their proportionate share of the April IDS unless the April IDS is revised as explained below in paragraph 6. If junior ground water users secured water for a reasonable carryover shortfall to an individual SWC member in the previous year, the current-year mitigation obligation to the individual SWC member will be reduced by the quantity of water secured for the reasonable carryover shortfall. The secured water will not be required to be delivered to the injured members of the SWC until the Time of Need.

5. Step 4: As soon as practical after the deadline for junior ground water users with approved mitigation plans to provide notice of secured water, the Director will issue an order curtailing junior ground water users who: (1) do not have approved mitigation plans; (2) fail to secure the required water consistent with their approved mitigation plans; or (3) otherwise fail to comply with their approved mitigation plans.[25]

[25] This presumes that any reasonable carryover obligation has been met, and that junior ground water users are not already under prior curtailment from deficiencies in meeting the previous year's obligation.

6. If, at any time prior to the Director's final determination of the April FS, the Director can determine with certainty that any member of the SWC has diverted more natural flow than predicted, or has accrued more storage than predicted, the Director will revise his initial, projected demand shortfall determination.

7. Step 5: If the storage allocations held by members of the SWC fill, there is no reasonable carryover shortfall. If the storage allocations held by members of the SWC do not fill, within fourteen (14) days following the publication of Water District 01's initial storage report, which typically occurs soon after the Day of Allocation,[26] the volume of water secured by junior ground water users to fulfill the reasonable carryover shortfall shall be made available to injured members of the SWC. The amount of reasonable carryover to be provided shall not exceed the empty storage space on the Day of Allocation for that entity. If water is owed in addition to the reasonable carryover shortfall volume, this water shall be delivered or assigned to members of the SWC at the Time of Need, described below. The Time of Need will be no earlier than the Day of Allocation.

8. Step 6: Approximately halfway through the irrigation season, but following the events described in Step 5, the Director will, for each member of the SWC: (1) recalculate RISD; (2) issue a revised FS and (3) estimate the Time of Need date.[27]

9. RISD will be calculated utilizing the project efficiency, BD, and the cumulative actual CWN determined up to that point in the irrigation season. The cumulative CWN volume will be calculated for all land irrigated with surface water within the boundaries of each member of the SWC. Volumetric values of CWN will be calculated using ET and precipitation values from the USBR's AgriMet program, irrigated areas provided by each entity, and crop distributions based on NASS data.

10. The FS for each SWC is the sum of the year-to-date actual natural flow diversions, the forecasted natural flow supply for the remainder of the season, and the storage allocation for each member of the SWC. The forecasted natural flow supply for the remainder of the season will be based on regression analysis. The storage allocation will be based on the actual preliminary storage allocations issued by the BOR and Water District 01. If the BOR and Water District 01 have not yet allocated stored water to spaceholders, the Department will predict the storage allocations based on an analogous year(s).

11. The calendar day determined to be the Time of Need is established by predicting the day in which the remaining storage allocation will be equal to reasonable carryover. The Time of Need will not be earlier than the Day of Allocation.

---

[26] The Day of Allocation is the time in the irrigation season when the Water District 01 watermaster can issue allocations to storage space holders after the reservoir system has achieved its maximum physical fill, maximum water right accrual, and any excess spill past Milner Dam has ceased. Tr. p. 902, lns. 7-25; p. 903, lns. 1-10.

[27] At the earliest established Time of Need for any member of the SWC, junior ground water users are required to provide remaining mitigation to all materially injured members of the SWC.

12. This information will be used to recalculate RISD and adjust the projected IDS for each member of the SWC. The Director will then issue revised RISD and DS values. Any increase to the projected IDS for each SWC entity is an additional mitigation obligation of the junior ground water users.

13. Upon a determination of an additional mitigation obligation, junior ground water users will be required to establish, to the satisfaction of the Director, their ability to secure a volume of storage water or to conduct other approved activities pursuant to an approved mitigation plan that will deliver the additional mitigation obligation water to the injured members of the SWC at the Time of Need. If junior ground water users fail or refuse to submit this information within fourteen (14) days from issuance of a Step 6 order, the Director will issue an order curtailing junior ground water users.[28] A transient ESPAM simulation will be run to determine the priority date to produce the necessary additional mitigation obligation volume by September 30 of the same year. Curtailment will be simulated within the area of common ground water supply, as described by CM Rule 50.01.

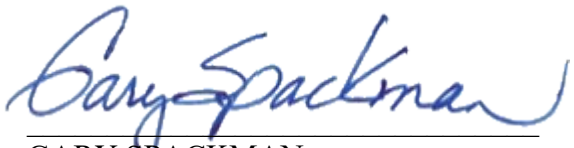
14. Step 7: Shortly before the estimated Time of Need, but following the events described in Steps 5 and 6, the Director will, for each member of the SWC: (1) recalculate RISD; (2) issue a revised FS; and (3) establish the Time of Need. The revised FS for each SWC entity is the sum of the year-to-date actual natural flow diversions, the forecasted natural flow supply for the remainder of the season, and the storage allocation for each member of the SWC. The forecasted natural flow supply for the remainder of the season will be based on analogous year(s) with similar Blackfoot to Milner reach gains. The storage allocation will be based on the actual preliminary storage allocations issued by the BOR and Water District 01.

15. This information will be used to recalculate RISD and adjust the projected IDS for each member of the SWC. RISD will be calculated utilizing the project efficiency, BD, and the cumulative actual CWN determined up to that point in the irrigation season. The Director will then issue revised RISD and IDS values.

16. A transient ESPAM simulation will be run to determine the priority date of water rights that must be curtailed to produce the demand shortfall volume by September 30 of the same year. Curtailment will be simulated within the area of common ground water supply, as described by CM Rule 50.01.

17. Step 8: At the Time of Need, junior ground water users are required to deliver to each injured member of the SWC the Step 7 revised IDS calculated at the Time of Need. Alternatively, any additional mitigation obligation calculated in Step 6 and Step 7 can be satisfied from each SWC member's reasonable carryover if (a) the reasonable carryover exceeds the additional mitigation obligation, and (b) the junior ground water users secure sufficient water to replace the reasonable carryover pursuant to an approved mitigation plan.

[28] This presumes that any reasonable carryover obligation has been met, and that junior ground water users are not already under prior curtailment from deficiencies in meeting the previous year's obligation.



18. The Director will review, at the end of the season, the volume and efficiencies of application of surface water, the amount of mitigation water delivered by junior ground water users, and may, in the exercise of his professional judgment, readjust the reasonable carryover shortfalls to reflect these considerations.

19. Step 9: Following the end of the irrigation season (on or before November 30), the Department will determine the total actual volumetric demand and total actual CWN for the entire irrigation season. This information will be used for the analysis of reasonable carryover shortfall, selection of future BLY, and for the refinement and continuing improvement of the method for future use.

20. On or before November 30, the Department will issue estimates of actual carryover and reasonable carryover shortfall volumes for all members of SWC. These estimates will be based on, but not limited to, the consideration of the best available water diversion and storage data from Water District 01, return flow monitoring, comparative years, and RISD. These estimates will establish the obligation of junior ground water users in providing water to the SWC for reasonable carryover shortfall. Fourteen (14) days following the issuance by the Department of reasonable carryover short fall obligations, junior ground water users will be required to establish, to the satisfaction of the Director, their ability to supply a volume of storage water or to conduct other approved mitigation activities that will provide water to the injured members of the SWC equal to the reasonable carryover shortfall for all injured members of the SWC. If junior ground water users cannot provide this information, the Director will issue an order curtailing junior ground water rights. A transient ESPAM simulation will be run to determine the priority date of water rights that must be curtailed to produce the reasonable carryover shortfall volume by September 30 of the following year. Curtailment will be simulated within the area of common ground water supply, as described by CM Rule 50.01.

IT IS FURTHER ORDERED that this Fifth Methodology Order supersedes all previously issued methodology orders in this matter.

Dated this _21st_ day of April 2023.

Administrative Assistant II

EXPLANATORY INFORMATION TO ACCOMPANY A FINAL ORDER

(To be used in connection with actions when a hearing was **not** held)

(Required by Rule of Procedure 740.02)

The accompanying order is a "**Final Order**" issued by the department pursuant to section 67-5246, Idaho Code.

PETITION FOR RECONSIDERATION

Any party may file a petition for reconsideration of a final order within fourteen (14) days of the service date of this order as shown on the certificate of service. **Note: The petition must be received by the Department within this fourteen (14) day period.** The department will act on a petition for reconsideration within twenty-one (21) days of its receipt, or the petition will be considered denied by operation of law. See section 67-5246(4), Idaho Code.

REQUEST FOR HEARING

Unless the right to a hearing before the director or the water resource board is otherwise provided by statute, any person who is aggrieved by the action of the director, and who has not previously been afforded an opportunity for a hearing on the matter shall be entitled to a hearing before the director to contest the action. The person shall file with the director, within fifteen (15) days after receipt of written notice of the action issued by the director, or receipt of actual notice, a written petition stating the grounds for contesting the action by the director and requesting a hearing. See section 42-1701A(3), Idaho Code. **Note: The request must be received by the Department within this fifteen (15) day period.**

APPEAL OF FINAL ORDER TO DISTRICT COURT

Pursuant to sections 67-5270 and 67-5272, Idaho Code, any party aggrieved by a final order or orders previously issued in a matter before the department may appeal the final order and all previously issued orders in the matter to district court by filing a petition in the district court of the county in which:

i. A hearing was held,
ii. The final agency action was taken,
iii. The party seeking review of the order resides, or
iv. The real property or personal property that was the subject of the agency action is located.

The appeal must be filed within twenty-eight (28) days of: a) the service date of the final order, b) the service date of an order denying petition for reconsideration, or c) the failure within twenty-one (21) days to grant or deny a petition for reconsideration, whichever is later. See section 67-5273, Idaho Code. The filing of an appeal to district court does not in itself stay the effectiveness or enforcement of the order under appeal.

Revised July 1, 2010

BEFORE THE DEPARTMENT OF WATER RESOURCES

OF THE STATE OF IDAHO

IN THE MATTER OF DISTRIBUTION OF WATER TO VARIOUS WATER RIGHTS HELD BY OR FOR THE BENEFIT OF A&B IRRIGATION DISTRICT, AMERICAN FALLS RESERVOIR DISTRICT #2, BURLEY IRRIGATION DISTRICT, MILNER IRRIGATION DISTRICT, MINIDOKA IRRIGATION DISTRICT, NORTH SIDE CANAL COMPANY, AND TWIN FALLS CANAL COMPANY	Docket No. CM-DC-2010-001 **FINAL ORDER REGARDING APRIL 2023 FORECAST SUPPLY** **(METHODOLOGY STEPS 1–3)**

FINDINGS OF FACT

1. On April 21, 2023, the Director of the Idaho Department of Water Resources ("Department") issued his *Fifth Amended Final Order Regarding Methodology for Determining Material Injury to Reasonable In-Season Demand and Reasonable Carryover* ("Methodology Order"). The Methodology Order established nine steps for determining material injury to members of the Surface Water Coalition ("SWC"). This order applies steps 1, 2, and 3 of the Methodology Order.

A. Step 1

2. By April 1 of each year, Step 1 requires members of the SWC to submit to the Department electronic shapefiles delineating the total anticipated irrigated acres for the upcoming year "or confirm in writing that the existing electronic shape file submitted by SWC has not varied by more than five percent." *Methodology Order* ¶ 1 at 39.

3. On February 6, 2023, the Department received a letter from American Falls Reservoir District #2 ("AFRD2"), stating that its total number of irrigated acres has not varied by more than five percent.

4. On March 2, 2023, Minidoka Irrigation District ("Minidoka") submitted its electronic shapefile delineating its total irrigated acres to the Department.

5. On March 10, 2023, the Department received a letter from A&B Irrigation District ("A&B"), Burley Irrigation District ("BID"), Milner Irrigation District ("Milner"), North Side Canal Company ("NSCC") and Twin Falls Canal Company ("TFCC"), stating that their total number of irrigated acres for 2023 will not vary by more than five percent from the electronic shapefiles submitted in prior years.

6. Based on the information submitted by the SWC, the Department will use the following total irrigated acres:

	Total Irrigated Acres[1]	Data Source
A&B	15,924	SRBA Partial Decree
AFRD2	62,361	SRBA Partial Decree
BID	46,035	2013 shapefile submitted by BID, reduced by Department for overlapping acres and acres outside of service area.
Milner	13,264	2010 service area shapefile, reduced by Department for overlapping acres and acres outside of service area.
Minidoka	75,093	SRBA Partial Decree
NSCC	154,067	SRBA Partial Decree
TFCC	194,732	2013 shapefile submitted by TFCC, reduced by Department for overlapping acres and acres outside of service area.

B. Step 2

7. Step 2 states that, within fourteen days of the issuance of the joint forecast prepared by the United States Bureau of Reclamation and the United States Army Corp of Engineers, the Director "will issue a final order predicting the April [Forecast Supply] for the water year for each SWC entity. The Director will compare the April [Forecast Supply] for each SWC entity to the [Baseline Demand] for each SWC entity to determine if a in-season demand shortfall ("IDS") is anticipated for the upcoming irrigation season." *Methodology Order* ¶ 3 at 40.

8. On April 7, 2023, the joint forecast ("Joint Forecast") was announced, predicting an unregulated inflow 3,700,000 acre-feet at the Snake River near Heise gage for the period of April through July. The forecasted flow volume equates to 112% percent of average.[2] The Joint Forecast "is generally as accurate a forecast as is possible using current data gathering and forecasting techniques." *Id.* ¶ 49 at 18 (citation omitted).

9. The Heise natural flow data from years 1990–2022 were data inputs for development of regression equations for A&B and Milner to predict the natural flow supply.[3] Data greater or less than two standard deviations from average were excluded from the regression development.

10. The April–July Heise natural flow data from the years 1990–2022 and Box Canyon November–March total discharge data for the period 1989–2022, were data inputs for development of multiple linear regression equations to predict the natural flow supplies for

[1] The number of irrigated acres used in this methodology order is the number of reported acres unless that number is larger than the decreed irrigated acres, and if so, then the decreed acres were used.

[2] The average is based on the years 1991-2020. The Joint Forecast relies on a "30-Year Climate Normal" to calculate an Average April through July runoff volume.

[3] Attached hereto, as Attachment A, are the regression analyses for each SWC entity used to predict natural flow supply.

AFRD2, BID, Minidoka, NSCC, and TFCC. *Methodology Order* ¶ 49 at 18. The U.S. Geological Survey measures and monitors the flow at the Box Canyon stream flow measurement gage. The Box Canyon November–March total discharge used by the Director in the regression models for 2023 totaled 91,898 acre-feet.

11. The storage allocations were predicted for each SWC member. As of April 11, 2023, preliminary water right accounting for the 2023 irrigation year had not been completed. Storage allocations were calculated using an average of actual storage allocations of analogous years. The Surface Water Supply Index (SWSI)[4], produced by the Natural Resources Conservation Service (NRCS), is calculated by summing reservoir carryover and the forecasted spring and summer streamflow runoff. The April 1 SWSI indicates the water supply in 1993 and 2016 are analogous to the water supply in 2023. Based on the analogous years, the Director anticipates SWC members will receive 95–100% of their allocation. The storage allocations are based on the anticipated allocations minus evaporation charges.

12. Based on the above, the Director projects as follows:

	Predicted Natural Flow Supply	Predicted Storage Allocation	Minidoka Credit Adjustment	Total Supply	BLY 2018	Shortfall
A&B	14,833	135,411		150,244	64,192	0
AFRD2	115,223	387,853	1,000	504,076	453,890	0
BID	109,313	221,713	5,130	336,156	262,211	0
Milner	18,347	88,047		106,393	58,417	0
Minidoka	156,468	342,620	8,370	507,458	354,851	0
NSCC	457,802	819,773	-7,750	1,269,825	1,026,661	0
TFCC	820,663	232,606	-6,750	1,046,519	1,121,717	75,200
				Total Projected Demand Shortfall (AF)		75,200

C. Step 3

13. Step 3 requires the following:

> Step 3: By May 1, or within fourteen (14) days from issuance of the final order predicting the April FS, whichever is later in time, junior ground water users with approved mitigation plans for delivery of water must secure, to the satisfaction of the Director, a volume of water equal to their proportionate share of the April IDS unless the April IDS is revised as explained below in paragraph 6. If junior ground water users secured water for a reasonable carryover shortfall to an individual SWC member in the previous year, the current-year mitigation obligation to the

[4] SWSI is a predictive indicator of the surface water available in a basin compared to historic supply. The SWSI is produced monthly by the Natural Resources Conservation Service (NRCS). *See* Nat. Res. Conserv'n Serv., U.S. Dep't of Agric., *Surface Water Supply Index (SWSI)*, https://www.nrcs.usda.gov/wps/portal/nrcs/detail/id/snow/waterproducts/?cid=stelprdb1240689 (last visited Apr. 20, 2022).

individual SWC member will be reduced by the quantity of water secured for the reasonable carryover shortfall. The secured water will not be required to be delivered to the injured members of the SWC until the Time of Need.

Methodology Order ¶ 4 at 40.

14. The predicted April DS for TFCC is 75,200 acre-feet. The total predicted DS is 75,200 acre-feet.

15. The Eastern Snake Plain Aquifer Model ("ESPAM") is used to predict the junior priority water rights that must be curtailed to produce the volume of water equal to the predicted April DS in the near Blackfoot to Minidoka reach. The ESPAM is updated periodically as new field measurements and advancements in modeling technology become available. ESPAM Version 2.2 ("ESPAM2.2") is the current version. ESPAM2.2 model documentation reports (including a model calibration report, a predictive uncertainty analysis, a superposition model scenario, and a curtailment scenario) were finalized on May 27, 2021. *See* Idaho Dep't of Water Res., *ESPAM2.2 Reports* (2021), https:// research.idwr.idaho.gov/files/projects/espam/ browse/ESPAM22_Reports/.

16. The Department ran ESPAM2.2 to predict the junior priority water rights within the area of common ground water supply that must be curtailed to produce the volume of water equal to the predicted April DS between the May 1 and September 30 of this irrigation season pursuant to the *Fifth Amended Final Order Regarding Methodology for Determining Material Injury to Reasonable In-Season Demand and Reasonable Carryover*. Ground water rights bearing priority dates later than December 30, 1953, must be curtailed to produce the volume of water equal to the predicted April DS in the near Blackfoot to Minidoka reach.

CONCLUSIONS OF LAW

1. The Fifth Judicial District Court, in and for the County of Minidoka, held that the evidentiary standard of proof to apply in conjunctive administration of hydraulically connected water rights is clear and convincing. *See* Mem. Decision & Order on Pets. for Jud. Rev., *A&B Irr. Dist., Inc. v. Idaho Dep't of Water Res.*, No. CV-2009-647 (Minidoka Cnty. Dist. Ct. Idaho May 4, 2010); Mem. Decision & Order on Pets. for Reh'g, *A&B Irr. Dist., Inc. v. Idaho Dep't of Water Res.*, No. CV-2009-647 (Minidoka Cnty. Dist. Ct. Idaho Nov. 2, 2010).

2. "Clear and convincing evidence refers to a degree of proof greater than a mere preponderance." *Idaho State Bar v. Topp*, 129 Idaho 414, 416, 925 P.2d 1113, 1115 (1996) (internal quotations removed). "Clear and convincing evidence is generally understood to be '[e]vidence indicating that the thing to be proved is highly probable or reasonably certain.'" *State v. Kimball*, 145 Idaho 542, 546, 181 P.3d 468, 472 (2008) (citing *In re Adoption of Doe*, 143 Idaho 188, 191, 141 P.3d 1057, 1060 (2006)); *see also Idaho Dep't of Health & Welfare v. Doe*, 150 Idaho 36, 41, 244 P.3d 180, 185 (2010).

3. The Director must utilize the best available technology for determining the impact of junior ground water diversions. *See Clear Springs Foods, Inc. v. Spackman*, 150 Idaho 790, 814,

252 P.3d 71, 95 (2011). ESPAM 1.1 and 2.1 are the model versions utilized previously in SWC delivery call proceedings. The Director determined that ESPAM 2.1 is the best available scientific tool for predicting the effects of ground water pumping. *See Idaho Ground Water Assoc. v. Idaho Dep't of Water Res.*, 160 Idaho 119, 124, 369 P.3d 897, 902 (2016). ESPAM 2.2 is the latest version of the ESPAM model. The improvements incorporated into ESPAM 2.2, as discussed in Finding of Fact 15, make it the best available scientific tool for predicting the effects of ground water pumping in this proceeding.

4. In 2023, the Director has sufficient information to quantify irrigated areas for each of the SWC members as required by Step 1.

5. The Joint Forecast predicts an unregulated inflow of 3,700,000 acre-feet at the Snake River near Heise gage for the period of April through July. The forecasted flow volume equates to 112% of average.

6. The April predicted DS is 75,200 acre-feet. Junior ground water users holding consumptive water rights bearing priority dates junior to December 30, 1953, within the Eastern Snake Plain Aquifer area of common ground water supply must mitigate for their proportionate share of the predicted DS in accordance with an approved mitigation plan.[5] Junior ground water users mitigating for their proportionate share of the predicted DS with a secured volume of water pursuant to an approved mitigation plan must, to the satisfaction of the Director, secure their proportionate share for delivery to the injured members of the SWC on or before May 5, 2023. There was a reasonable carryover shortfall of 49,309 acre-feet in the fall of 2022. However, because junior ground water users did not secure any mitigation water for a carryover shortfall, there is no adjustment to the mitigation obligation.

7. If, on or before May 5 2023, ground water users holding consumptive water rights bearing priority dates junior to December 30, 1953, within the Eastern Snake Plain Aquifer area of common ground water supply fail to establish, to the satisfaction of the Director, that they can mitigate for their proportionate share of the predicted DS of 75,200 acre-feet in accordance with an approved mitigation plan, the Director will issue an order curtailing the junior-priority ground water user. Junior ground water users who are mitigating with a secured volume of water are not required to assign the secured volume of water until after the Director issues a subsequent order requiring assignment of the water.

---

[5] There are seven approved mitigation plans in place responding to the SWC delivery call filed by: 1) A&B Irrigation District, 2) Southwest Irrigation District and Goose Creek Irrigation District (collectively, "SWID"), 3) the Idaho Ground Water Appropriators, Inc. ("IGWA"), 4) certain cities commonly referred to as the "Coalition of Cities", and 5) certain entities commonly referred to as the "Water Mitigation Coalition." A&B Irrigation District's proportionate share of the predicted DS of 75,200 acre-feet is 458 acre-feet. Due to the nature of the mitigation plans for SWID, the Coalition of Cities and the Water Mitigation Coalition, these entities do not need to establish that they can mitigate for their proportionate share of the predicted DS. IGWA has two approved mitigation plans. If IGWA is in compliance with mitigation plan CM-MP-2016-001, IGWA does not need to establish that it can mitigate for its proportionate share of the predicted DS. If IGWA seeks to provide mitigation by delivery of storage water as approved in mitigation plan CM-MP-2009-007, IGWA's proportionate share of the predicted DS of 75,198 acre-feet is 63,645 acre-feet.

8. If, at any time prior to the Director's final determination of the April Forecast Supply, the Director can determine with certainty that any member of the SWC has diverted more natural flow than predicted, or has accrued more storage than predicted, the Director will revise his initial, predicted DS determination.

ORDER

Based upon and consistent with the foregoing, IT IS HEREBY ORDERED as follows:

The Director predicts an in-season DS of 75,200 acre-feet. On or before May 5, 2023, ground water users holding consumptive water rights bearing priority dates junior to December 30, 1953, within the Eastern Snake Plain Aquifer area of common ground water supply shall establish, to the satisfaction of the Director, that they can mitigate for their proportionate share of the predicted DS of 75,200 acre-feet in accordance with an approved mitigation plan. If a junior ground water user cannot establish, to the satisfaction of the Director, that they can mitigate for their proportionate share of the predicted DS of 75,200 acre-feet in accordance with an approved mitigation plan, the Director will issue an order curtailing the junior-priority ground water user.

Dated this 21st day of April 2023.

GARY SPACKMAN
Director

CERTIFICATE OF SERVICE

EXPLANATORY INFORMATION TO ACCOMPANY A FINAL ORDER

(To be used in connection with actions when a hearing was **not** held)

(Required by Rule of Procedure 740.02)

The accompanying order is a **"Final Order"** issued by the department pursuant to section 67-5246, Idaho Code.

PETITION FOR RECONSIDERATION

Any party may file a petition for reconsideration of a final order within fourteen (14) days of the service date of this order as shown on the certificate of service. **Note: The petition must be received by the Department within this fourteen (14) day period.** The department will act on a petition for reconsideration within twenty-one (21) days of its receipt, or the petition will be considered denied by operation of law. See section 67-5246(4), Idaho Code.

REQUEST FOR HEARING

Unless the right to a hearing before the director or the water resource board is otherwise provided by statute, any person who is aggrieved by the action of the director, and who has not previously been afforded an opportunity for a hearing on the matter shall be entitled to a hearing before the director to contest the action. The person shall file with the director, within fifteen (15) days after receipt of written notice of the action issued by the director, or receipt of actual notice, a written petition stating the grounds for contesting the action by the director and requesting a hearing. See section 42-1701A(3), Idaho Code. **Note: The request must be received by the Department within this fifteen (15) day period.**

APPEAL OF FINAL ORDER TO DISTRICT COURT

Pursuant to sections 67-5270 and 67-5272, Idaho Code, any party aggrieved by a final order or orders previously issued in a matter before the department may appeal the final order and all previously issued orders in the matter to district court by filing a petition in the district court of the county in which:

i. A hearing was held,
ii. The final agency action was taken,
iii. The party seeking review of the order resides, or
iv. The real property or personal property that was the subject of the agency action is located.

The appeal must be filed within twenty-eight (28) days of: a) the service date of the final order, b) the service date of an order denying petition for reconsideration, or c) the failure within twenty-one (21) days to grant or deny a petition for reconsideration, whichever is later. See section 67-5273, Idaho Code. The filing of an appeal to district court does not in itself stay the effectiveness or enforcement of the order under appeal.

Revised July 1, 2010

BEFORE THE DEPARTMENT OF WATER RESOURCES

OF THE STATE OF IDAHO

IN THE MATTER OF DISTRIBUTION OF WATER TO VARIOUS WATER RIGHTS HELD BY OR FOR THE BENEFIT OF A&B IRRIGATION DISTRICT, AMERICAN FALLS RESERVOIR DISTRICT #2, BURLEY IRRIGATION DISTRICT, MILNER IRRIGATION DISTRICT, MINIDOKA IRRIGATION DISTRICT, NORTH SIDE CANAL COMPANY, AND TWIN FALLS CANAL COMPANY	Docket No. CM-DC-2010-001 **FINAL ORDER REGARDING APRIL 2022 FORECAST SUPPLY** **(METHODOLOGY STEPS 1–3)**

FINDINGS OF FACT

1. On April 19, 2016, the Director ("Director") of the Idaho Department of Water Resources ("Department") issued his *Fourth Amended Final Order Regarding Methodology for Determining Material Injury to Reasonable In-Season Demand and Reasonable Carryover* ("Methodology Order"). The Methodology Order established nine steps for determining material injury to members of the Surface Water Coalition ("SWC"). This order applies steps 1, 2, and 3 of the Methodology Order.

A. Step 1

2. By April 1 of each year, Step 1 requires members of the SWC to submit to the Department electronic shapefiles delineating the total anticipated irrigated acres for the upcoming year "or confirm in writing that the existing electronic shape file submitted by SWC has not varied by more than five percent." *Methodology Order* ¶ 1 at 35.

3. On March 8, 2022, the Department received a letter from A&B Irrigation District ("A&B"), Burley Irrigation District ("BID"), Milner Irrigation District ("Milner"), North Side Canal Company ("NSCC") and Twin Falls Canal Company ("TFCC"), stating that their total number of irrigated acres for 2022 will not vary by more than five percent from the electronic shapefiles submitted in prior years.

4. On March 9, 2022, the Department received a letter from American Falls Reservoir District #2 ("AFRD2"), stating that its total number of irrigated acres has not varied by more than five percent.

5. On April 1, 2022, Minidoka Irrigation District ("Minidoka") submitted its electronic shapefile delineating its total irrigated acres to the Department.

6. Based on the information submitted by the SWC, the Department will use the following total irrigated acres:

	Total Irrigated Acres	Data Source
A&B	15,924	SRBA Partial Decree
AFRD2	62,361	SRBA Partial Decree
BID	46,035	2013 shapefile submitted by BID, reduced by Department for overlapping acres and acres outside of service area.
Milner	13,335	SRBA Partial Decree
Minidoka	75,340	2022 shapefile submitted by Minidoka, reduced by Department for overlapping acres and acres outside of service area.
NSCC	154,067	SRBA Partial Decree
TFCC	194,732	2013 shapefile submitted by TFCC, reduced by Department for overlapping acres and acres outside of service area.

B. Step 2

7. Step 2 states that, within fourteen days of the issuance of the joint forecast ("Joint Forecast") prepared by the United States Bureau of Reclamation and the United States Army Corp of Engineers, the Director "will issue a final order predicting the April [Forecast Supply] for the water year for each SWC entity. The Director will compare the April [Forecast Supply] for each SWC entity to the [Baseline Demand] for each SWC entity to determine if a demand shortfall ("DS") is anticipated for the upcoming irrigation season." *Methodology Order* ¶ 3 at 36.

8. On April 6, 2022, the Joint Forecast was announced, predicting an unregulated inflow 2,150,000 acre-feet at the Snake River near Heise gage for the period of April through July. The forecasted flow volume equates to 65% percent of average.[1] The Joint Forecast "is generally as accurate a forecast as is possible using current data gathering and forecasting techniques." *Id.* ¶ 49 at 17 (citation omitted).

9. The Heise natural flow data from years 1990–2021 were data inputs for development of regression equations for A&B and Milner to predict the natural flow supply.[2] Data greater or less than two standard deviations from average were excluded from the regression development.

10. The April-July Heise natural flow data from the years 1990–2021 and Box Canyon November-March total discharge data for the period 1989–2021, were data inputs for development of multiple linear regression equations to predict the natural flow supplies for AFRD2, BID, Minidoka, NSCC, and TFCC. *Methodology Order* ¶ 49 at 17–18. The U.S.

[1] The average is based on the years1991-2020. The Joint Forecast relies on a "30-Year Climate Normal" to calculate an Average April through July runoff volume.

[2] Attached hereto, as Attachment A, are the regression analyses for each SWC entity used to predict natural flow supply.

Geological Survey measures and monitors the flow at the Box Canyon stream flow measurement gage. The Box Canyon November-March total discharge used by the Director in the regression models for 2022 totaled 93,524 acre-feet.

11. The storage allocations were predicted for each SWC member. As of April 1, 2022, preliminary water right accounting indicates the water rights for Lake Walcott, Jackson Lake 1910, Palisades Winter Water Savings, Island Park 1921, American Falls Winter Water Savings, and Henry's Lake 1965 space are satisfied. The remaining reservoir rights are 1,603,003 acre-feet from satisfaction. The Surface Water Supply Index (SWSI)[3] indicates the water supply in 2001, 2002, and 2004 are analogous to the water supply in 2022. Based on the analogous years, the Director anticipates the remaining reservoir rights for Jackson Lake, Palisades and American Falls will be 45-95% satisfied and each SWC member will receive 83-96% of their allocation. The storage allocations are based on the anticipated allocations minus evaporation charges.

12. Based on the above, the Director projects as follows:

	Predicted Natural Flow Supply	Predicted Storage Allocation	Minidoka Credit Adjustment	Total Supply	BLY 06/08/12	Shortfall
A&B	467	122,306		122,773	59,992	0
AFRD2	16,941	364,890	1,000	382,831	427,672	44,800
BID	64,881	213,484	5,130	283,494	251,531	0
Milner	3,050	72,450		75,500	47,135	0
Minidoka	88,905	301,293	8,370	398,568	369,492	0
NSCC	246,664	744,164	-7,750	983,078	978,888	0
TFCC	741,869	207,120	-6,750	942,239	1,060,011	117,800
				Total Projected Demand Shortfall (AF)		162,600

C. Step 3

13. Step 3 requires the following:

> Step 3: By May 1, or within fourteen (14) days from issuance of the final order predicting the April FS, whichever is later in time, junior ground water users with approved mitigation plans for delivery of water must secure, to the satisfaction of the Director, a volume of water equal to their proportionate share of the April DS unless the April DS is revised as explained below in paragraph 6. If junior ground water users secured water for a reasonable carryover shortfall to an individual SWC member in the previous year, the current-year mitigation obligation to the individual SWC member will be reduced by the quantity of water secured for the

[3] SWSI is a predictive indicator of the surface water available in a basin compared to historic supply. The SWSI is produced monthly by the Natural Resources Conservation Service (NRCS). *See* Nat. Res. Conserv'n Serv., U.S. Dep't of Agric., *Surface Water Supply Index (SWSI)*, https://www.nrcs.usda.gov/wps/portal/nrcs/detail/id/snow/waterproducts/?cid=stelprdb1240689 (last visited Apr. 20, 2022).

reasonable carryover shortfall. The secured water will not be required to be delivered to the injured members of the SWC until the Time of Need.

Methodology Order ¶ 4 at 36.

14. The predicted April DS for AFRD2 is 44,800 acre-feet and TFCC is 117,800 acre-feet. The total predicted DS is 162,600 acre-feet.

15. The Eastern Snake Plain Aquifer Model ("ESPAM") is used to predict the junior priority water rights that must be curtailed to produce the volume of water equal to the predicted April DS in the near Blackfoot to Minidoka reach. The ESPAM is updated periodically as new field measurements and advancements in modeling technology become available. ESPAM Version 2.2 ("ESPAM2.2") superseded Version 2.1. Improvements to the ground water flow model in ESPAM2.2 were identified and prioritized in collaboration with the Eastern Snake Hydrologic Modeling Committee (ESHMC). Significant improvements incorporated into ESPAM2.2 included extension of the calibration period to include water years 2009 through 2018, improved representation of aquifer recharge in the vicinity of the Big and Little Wood Rivers, improved representation of aquifer interaction with the Heise to Shelley reach of the Snake River, and improved representation of aquifer interaction with the near Blackfoot to Minidoka reach of the Snake River. *See* Jennifer Sukow, Idaho Dep't of Water Res., *Model Calibration Report: Eastern Snake Plain Aquifer Model Version 2.2* (2021), https://research.idwr.idaho.gov/files/projects/espam/browse/ESPAM22_Reports/ModelCalibrationRpt/ModelCalibration22_Final.pdf. The latter included improved spatial representation of aquifer discharge to the lower Portneuf River and numerous spring-fed creeks in the vicinity of American Falls Reservoir. The calibrated ESPAM2.2 was provided to ESHMC members for review on August 25, 2020, and was discussed in committee meetings on September 9, 2020, and October 28, 2020. The ESHMC adopted Version 2.2 of the ground water flow model during the October 28, 2020, meeting. ESPAM2.2 model documentation reports (including a model calibration report, a predictive uncertainty analysis, a superposition model scenario, and a curtailment scenario) were finalized on May 27, 2021. *See* Idaho Dep't of Water Res., *ESPAM2.2 Reports* (2021), https://research.idwr.idaho.gov/files/projects/espam/ browse/ESPAM22_Reports/.

16. The Department ran ESPAM2.2 to predict the junior priority water rights within the area of common ground water supply that must be curtailed to produce the volume of water equal to the predicted April DS at steady state. Ground water rights bearing priority dates later than December 25, 1979, must be curtailed to produce the volume of water equal to the predicted April DS in the near Blackfoot to Minidoka reach.

CONCLUSIONS OF LAW

1. The Fifth Judicial District Court, in and for the County of Minidoka, held that the evidentiary standard of proof to apply in conjunctive administration of hydraulically connected water rights is clear and convincing. *See* Mem. Decision & Order on Pets. for Jud. Rev., *A&B Irr. Dist., Inc. v. Idaho Dep't of Water Res.*, No. CV-2009-647 (Minidoka Cnty. Dist. Ct. Idaho May 4, 2010); Mem. Decision & Order on Pets. for Reh'g, *A&B Irr. Dist., Inc. v. Idaho Dep't of Water Res.*, No. CV-2009-647 (Minidoka Cnty. Dist. Ct. Idaho Nov. 2, 2010).

2. "Clear and convincing evidence refers to a degree of proof greater than a mere preponderance." *Idaho State Bar v. Topp*, 129 Idaho 414, 416, 925 P.2d 1113, 1115 (1996) (internal quotations removed). "Clear and convincing evidence is generally understood to be '[e]vidence indicating that the thing to be proved is highly probable or reasonably certain.'" *State v. Kimball*, 145 Idaho 542, 546, 181 P.3d 468, 472 (2008) (citing *In re Adoption of Doe*, 143 Idaho 188, 191, 141 P.3d 1057, 1060 (2006)); *see also Idaho Dep't of Health & Welfare v. Doe*, 150 Idaho 36, 41, 244 P.3d 180, 185 (2010).

3. The Director must utilize the best available technology for determining the impact of junior ground water diversions. *See Clear Springs Foods, Inc. v. Spackman*, 150 Idaho 790, 816, 252 P.3d 71, 97 (2011). ESPAM 1.1 and 2.1 are the model versions utilized previously in SWC delivery call proceedings. The Director determined that ESPAM 2.1 is the best available scientific tool for predicting the effects of ground water pumping. *See Idaho Ground Water Assoc. v. Idaho Dep't of Water Res.*, 160 Idaho 119, 124, 369 P.3d 897, 902 (2016). ESPAM 2.2 is the latest version of the ESPAM model. The improvements incorporated into ESPAM 2.2, as discussed in Finding of Fact 15, make it the best available scientific tool for predicting the effects of ground water pumping in this proceeding.

4. In 2022, the Director has sufficient information to quantify irrigated areas for each of the SWC members as required by Step 1.

5. The Joint Forecast predicts an unregulated inflow of 2,150,000 acre feet at the Snake River near Heise gage for the period of April through July. The forecasted flow volume equates to 65% of average.

6. The April predicted DS is 162,600 acre-feet. Junior ground water users holding consumptive water rights bearing priority dates junior to December 25, 1979, within the Eastern Snake Plain Aquifer area of common ground water supply must mitigate for their proportionate share of the predicted DS in accordance with an approved mitigation plan.[4] Junior ground water users mitigating for their proportionate share of the predicted DS with a secured volume of water pursuant to an approved mitigation plan must, to the satisfaction of the Director, secure their proportionate share for delivery to the injured members of the SWC on or before May 1, 2022. There was a reasonable carryover shortfall of 64,647 acre-feet in the fall of 2021. However, because junior ground water users did not secure any mitigation water for a carryover shortfall, there is no adjustment to the mitigation obligation.

7. If, on or before May 1, 2022, ground water users holding consumptive water rights bearing priority dates junior to December 25, 1979, within the Eastern Snake Plain Aquifer area of common ground water supply fail to establish, to the satisfaction of the Director, that they can mitigate for their proportionate share of the predicted DS of 162,600 acre-feet in accordance with

[4] There are seven approved mitigation plans in place responding to the SWC delivery call filed by: 1) A&B Irrigation District, 2) Southwest Irrigation District and Goose Creek Irrigation District (collectively, "SWID"), 3) the Idaho Ground Water Appropriators, Inc. ("IGWA"), 4) certain cities commonly referred to as the "Coalition of Cities", and 5) certain entities commonly referred to as the "Water Mitigation Coalition." A&B Irrigation District's proportionate share of the predicted DS of 162,600 acre-feet is 2,542 acre-feet. Due to the nature of the mitigation plans for SWID, IGWA, the Coalition of Cities and the Water Mitigation Coalition, these entities do not need to establish that they can mitigate for their proportionate share of the predicted DS.

an approved mitigation plan, the Director will issue an order curtailing the junior-priority ground water user. Junior ground water users who are mitigating with a secured volume of water are not required to assign the secured volume of water until after the Director issues a subsequent order requiring assignment of the water.

8. If, at any time prior to the Director's final determination of the April Forecast Supply, the Director can determine with certainty that any member of the SWC has diverted more natural flow than predicted, or has accrued more storage than predicted, the Director will revise his initial, predicted DS determination.

ORDER

Based upon and consistent with the foregoing, IT IS HEREBY ORDERED as follows:

The Director predicts an in-season DS of 162,600 acre-feet. On or before May 1, 2022, ground water users holding consumptive water rights bearing priority dates junior to December 25, 1979, within the Eastern Snake Plain Aquifer area of common ground water supply shall establish, to the satisfaction of the Director, that they can mitigate for their proportionate share of the predicted DS of 162,600 acre-feet in accordance with an approved mitigation plan. If a junior ground water user cannot establish, to the satisfaction of the Director, that they can mitigate for their proportionate share of the predicted DS of 162,600 acre-feet in accordance with an approved mitigation plan, the Director will issue an order curtailing the junior-priority ground water user.

Dated this 20th day of April 2022.

GARY SPACKMAN
Director

EXPLANATORY INFORMATION TO ACCOMPANY A FINAL ORDER

(To be used in connection with actions when a hearing was **not** held)

(Required by Rule of Procedure 740.02)

The accompanying order is a "**Final Order**" issued by the department pursuant to section 67-5246, Idaho Code.

PETITION FOR RECONSIDERATION

Any party may file a petition for reconsideration of a final order within fourteen (14) days of the service date of this order as shown on the certificate of service. **Note: The petition must be received by the Department within this fourteen (14) day period.** The department will act on a petition for reconsideration within twenty-one (21) days of its receipt, or the petition will be considered denied by operation of law. See section 67-5246(4), Idaho Code.

REQUEST FOR HEARING

Unless the right to a hearing before the director or the water resource board is otherwise provided by statute, any person who is aggrieved by the action of the director, and who has not previously been afforded an opportunity for a hearing on the matter shall be entitled to a hearing before the director to contest the action. The person shall file with the director, within fifteen (15) days after receipt of written notice of the action issued by the director, or receipt of actual notice, a written petition stating the grounds for contesting the action by the director and requesting a hearing. See section 42-1701A(3), Idaho Code. **Note: The request must be received by the Department within this fifteen (15) day period.**

APPEAL OF FINAL ORDER TO DISTRICT COURT

Pursuant to sections 67-5270 and 67-5272, Idaho Code, any party aggrieved by a final order or orders previously issued in a matter before the department may appeal the final order and all previously issued orders in the matter to district court by filing a petition in the district court of the county in which:

i. A hearing was held,
ii. The final agency action was taken,
iii. The party seeking review of the order resides, or
iv. The real property or personal property that was the subject of the agency action is located.

The appeal must be filed within twenty-eight (28) days of: a) the service date of the final order, b) the service date of an order denying petition for reconsideration, or c) the failure within twenty-one (21) days to grant or deny a petition for reconsideration, whichever is later. See section 67-5273, Idaho Code. The filing of an appeal to district court does not in itself stay the effectiveness or enforcement of the order under appeal.

Revised July 1, 2010

EXHIBIT 306

BEFORE THE DEPARTMENT OF WATER RESOURCES

OF THE STATE OF IDAHO

IN THE MATTER OF DISTRIBUTION OF WATER TO VARIOUS WATER RIGHTS HELD BY OR FOR THE BENEFIT OF A&B IRRIGATION DISTRICT, AMERICAN FALLS RESERVOIR DISTRICT #2, BURLEY IRRIGATION DISTRICT, MILNER IRRIGATION DISTRICT, MINIDOKA IRRIGATION DISTRICT, NORTH SIDE CANAL COMPANY, AND TWIN FALLS CANAL COMPANY	Docket No. CM-DC-2010-001 ***FOURTH AMENDED* FINAL ORDER REGARDING METHODOLOGY FOR DETERMINING MATERIAL INJURY TO REASONABLE IN-SEASON DEMAND AND REASONABLE CARRYOVER**

BACKGROUND

On June 23, 2010, the Director ("Director") of the Idaho Department of Water Resources ("Department") issued his *Second Amended Final Order Regarding Methodology for Determining Material Injury to Reasonable In-Season Demand and Reasonable Carryover* ("Second Methodology Order"). The Second Methodology Order explained how the Director would determine material injury to storage and natural flow water rights of members of the Surface Water Coalition ("SWC").[1] The SWC, the Idaho Ground Water Appropriators, Inc. ("IGWA"), and the City of Pocatello filed petitions seeking judicial review of the Second Methodology Order and its subsequent application. The petitions were consolidated with Gooding County Case No. CV-2010-382.[2]

On September 26, 2014, District Court Judge Eric Wildman issued his *Memorandum Decision and Order on Petitions for Judicial Review* ("Methodology Remand Order") in Gooding County Consolidated Case No. CV-2010-382. The Court "affirmed in part and set aside in part" the Second Methodology Order. *Methodology Remand Order* at 48. The Court remanded the Second Methodology Order to the Director for further proceedings as necessary. *Id.* The Court identified six general topics on remand. The six topics are margin headings in the following text and are discussed below.

[1] The SWC is comprised of A&B District, American Falls Reservoir District #2, Burley Irrigation District, Milner Irrigation District, Minidoka Irrigation District, North Side Canal Company, and Twin Falls Canal Company. Each entity holds separate senior surface natural flow water rights and has separate storage contracts for storage water space in the reservoirs.

[2] The following cases were consolidated with Gooding County Case No. CV-2010-382: Gooding County Cases CV-2010-383, CV-2010-384, CV-2010-387, CV-2010-388, Twin Falls County Cases CV-2010-3403, CV-2010-5520, CV-2010-5946, CV-2012-2096, CV-2013-2305, CV-2013-4417, and Lincoln County Case CV-2013-155.

Remedy for Material Injury to SWC Irrigation Season Natural Flow and Storage Water Rights

The Court held the Second Methodology Order failed to "provide a proper remedy for material injury to reasonable in-season demand when taking into account changing conditions." *Methodology Remand Order* at 10. If material injury to the SWC's irrigation season water rights is greater than originally determined by the Director in April, the injury must be remedied through either curtailment or mitigation at the time of the additional determination of injury. *Id.*

The Court also stated that, when taking into account changing conditions, the Director must "apply his established procedure as written or further define and/or refine the procedure so that [SWC] members relying on the procedure know when to anticipate its application and are able to plan accordingly." *Id.* at 40.

The Court held "[t]he Director may require use of reasonable carryover pursuant to a properly enacted mitigation plan that contains appropriate contingency provisions to protect senior rights." *Id.* at 16. In conjunction with a mitigation plan, the Director can require the SWC "rely on its reasonable carryover provided that: 1) existing carryover storage allocations meet or exceed the additional shortfall to the revised reasonable in-season demand; and 2) junior users secure a commitment at that time for a volume of water equal to the shortfall to the revised reasonable in-season demand to be provided the following season if necessary." *Id.*

Supplemental Ground Water Adjustment

The Court affirmed that supplemental ground water is a factor the Director has the authority to consider in the context of a delivery call. *Id.* at 18. However, administration "to less than the full amount of acres set forth on the face of the [SWC's] Partial Decrees. . . must be supported by clear and convincing evidence." *Id.* at 19. The Director's "assignment of an entity wide split for each member of the [SWC] of the ground water fraction to the surface water fraction is not supported by substantial evidence in the record." *Id.*

Predictors for Twin Falls Canal Company

The Court held the Joint Forecast prediction does not accurately predict water supply for the Twin Falls Canal Company ("TFCC"), and remanded the issue back to the Department for further proceedings as necessary. *Id.* at 20.

Crop Distribution Data

The Court affirmed the Director's use of the U.S. Department of Agriculture's 1990-2008 National Agricultural Statistics Service data for determining crop distributions but also encouraged the Director to "take into account available data reflecting current cropping patterns." *Id.* at 21.

ESPA Model Boundary

The Court concluded the Second Methodology Order "wrongly uses the ESPA Model boundary, instead of the boundary of the area of common water supply, to determine a curtailment priority date." *Id.* at 24.

Mitigation for Reasonable Carryover Shortfall

Step 10 of the Second Methodology Order offered an alternative to supplying the full volume of reasonable carryover shortfall established in Step 9. Under Step 10, junior ground water users could request that the Department model the transient impacts of the proposed curtailment. Junior water right holders could alternatively mitigate modeled transient depletions over a period of years. The Court remanded Step 10 to the Department, concluding that when the Director determines a shortfall to reasonable carryover and a corresponding mitigation obligation, the alternative of mitigating for transient future simulated reach gains resulting from modeled curtailment needs to be further justified. *Id.* at 28. The Court questioned the "viability of phased curtailment as a justification" for Step 10. *Id.*

ADDITIONAL BACKGROUND AND SUMMARY

On April 17, 2015, the Director issued the *Third Amended Order Regarding Methodology for Determining Material Injury to Reasonable In-Season Demand and Reasonable Carryover* ("Third Methodology Order").

On April 30, 2015, the City of Pocatello filed the *City of Pocatello's Request for Hearing, Motion to Authorize Discovery and Request for Stay* requesting the Director hold a status conference to schedule a hearing for the Third Methodology Order, issue an order authorizing discovery, and stay the hearing for six months. On April 30, 2015, IGWA filed a *Petition for Reconsideration and Clarification of the Third Methodology Order.*

On May 8, 2015, the SWC and IGWA filed the *Surface Water Coalition and IGWA Stipulation and Joint Motion Regarding April As Applied Order and Third Methodology Order* requesting the Director withdraw the Third Methodology Order. On May 8, 2015, the Director issued the *Order Approving Stipulation and Granting Joint Motion* withdrawing the Third Methodology Order.

On March 9, 2016, the SWC and IGWA filed the *Surface Water Coalition's and IGWA's Stipulated Motion to Reinstate the Third Amended Order Regarding Methodology for Determining Material Injury to Reasonable In-Season Demand and Reasonable Carryover* ("Stipulated Motion"). The SWC and IGWA requested the Director reinstate the Third Methodology Order and "[p]roceed with conjunctive administration for 2016 under the SWC delivery call." *Stipulated Motion* at 3. On March 18, 2016, Pocatello filed the *City of Pocatello's Response to SWC's and IGWA's Stipulated Motion to Reinstate the Third Methodology Order, and Motion* ("Response"). Pocatello did "not object to reinstating for the 2016 irrigation season" the Third Methodology Order. *Response* at 2.

On April 19, 2016, the Director issued an *Order on Motions Re: Third Methodology Order*. The Director granted the SWC and IGWA's request to reinstate the Third Methodology Order, but explained the order would be issued as the *Fourth Amended Final Order Regarding Methodology for Determining Material Injury to Reasonable In-Season Demand and Reasonable Carryover* ("Fourth Methodology Order").

The purpose of the Fourth Methodology Order is to establish the Director's methodology for determining material injury to storage and natural flow water rights either held by or committed to members of the SWC consistent with the Court's holding in the Methodology Remand Order.

FINDINGS OF FACT

I. Overview of the Methodology for Determining Material Injury to Water Rights by Determining Reasonable In-Season Demand and Reasonable Carryover

1. The methodology for determining material injury to water rights by determining reasonable in-season demand ("RISD") and reasonable carryover should be based on updated data, the best available science, analytical methods, and the Director's professional judgment as manager of the state's water resources. In the future, climate may vary and conditions may change; therefore, the methodology may need to be adjusted to consider a different baseline year or years ("BLY").

2. In-season demand shortfall will be computed by subtracting RISD from the forecast supply ("FS"). In-season demand shortfall is computed using the following equation:

- In-Season Demand Shortfall = FS – RISD

3. If the FS is greater than the RISD, there is no demand shortfall. If the FS is less that the RISD, the negative difference is the demand shortfall. Initially, RISD will be equal to the historic demands associated with a BLY as selected by the Director, but will be corrected during the season to account for variations in climate and water supply between the BLY and actual conditions.

4. Reasonable carryover shortfall will be computed by subtracting reasonable carryover from actual carryover, where reasonable carryover is defined as the difference between a baseline year demand ("BD") and projected typical dry year supply. Reasonable carryover shortfall will be computed using the following equation:

- Reasonable Carryover Shortfall = Actual Carryover – Reasonable Carryover

5. If actual carryover exceeds the reasonable carryover, there is no reasonable carryover shortfall. In contrast, if reasonable carryover exceeds the actual carryover, the negative difference is the reasonable carryover shortfall.

6. The concepts underlying the selection of the BLY, determination of in-season demand shortfall, and reasonable carryover shortfall will be discussed in detail below.

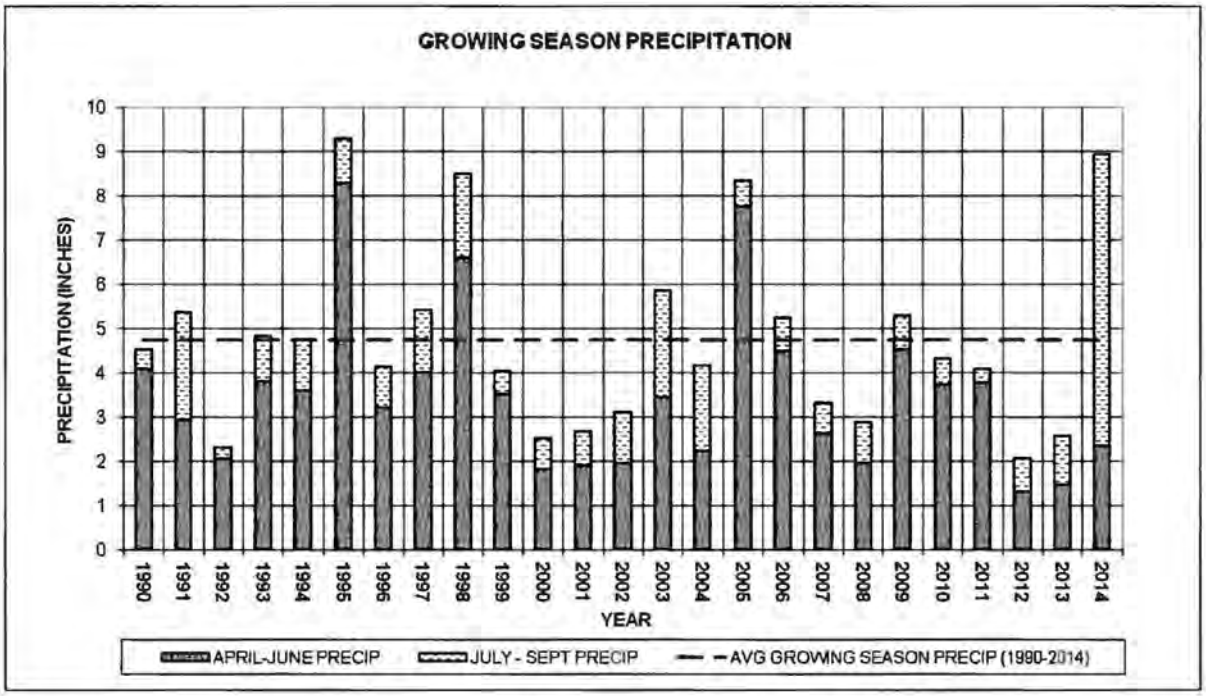
II. In-Season Demand Shortfall

A. Considerations for the Selection of a Baseline Year

7. A BLY is a year or average of years when irrigation demand represents conditions that can be utilized to predict need in the current year of irrigation at the start of the irrigation season. The purpose in predicting need is to project material injury at the start of the season.

8. A BLY is selected by analyzing three factors: (1) climate; (2) available water supply; and (3) irrigation practices. R. Vol. 37 at 7098.[3] To capture current irrigation practices, identification of a BLY is limited to years subsequent to 1999. *Id.* at 7096.

9. The historic diversion volumes from the BLY, along with the predicted supply forecast at the start of the irrigation season, are inputs to predict the initial in-season demand shortfall, where demand shortfall is the difference between the BD and the FS. Demand shortfall increases in magnitude as the difference between BD and FS increases. Demand shortfall increases with increases in BD, decreases in FS, or both. Assuming constant irrigation practices, crop distributions, and total irrigated acres, demand for irrigation water typically increases in years of higher temperature, higher evapotranspiration ("ET"), and lower precipitation. If water demand data is averaged for several years and these averages are the basis to predict demand shortfall at the start of the season, in a high water demand year, these averages may often under-predict the demand shortfall. In a high water demand year, under-prediction of demand shortfall might be acceptable if the junior priority ground water right holders and the senior priority surface water right holders shared equally in the risk of water shortages. Equality in sharing the risk will not adequately protect the senior priority surface water right holder from injury. Actual demand shortfalls to a senior surface water right holder resulting from predictions at the start of the irrigation season based on average data unreasonably shifts the risk of shortage to the senior surface water right holder. Therefore, a BLY should represent a year(s) of above average diversions, and should avoid years of below average diversions. An above average diversion year(s) selected as the BLY should also represent a year(s) of above average temperatures and ET, and below average precipitation to ensure that increased diversions were a function of crop water need and not other factors. In addition, actual supply should be analyzed to assure that the BLY is not a year of limited supply.



i. Climate

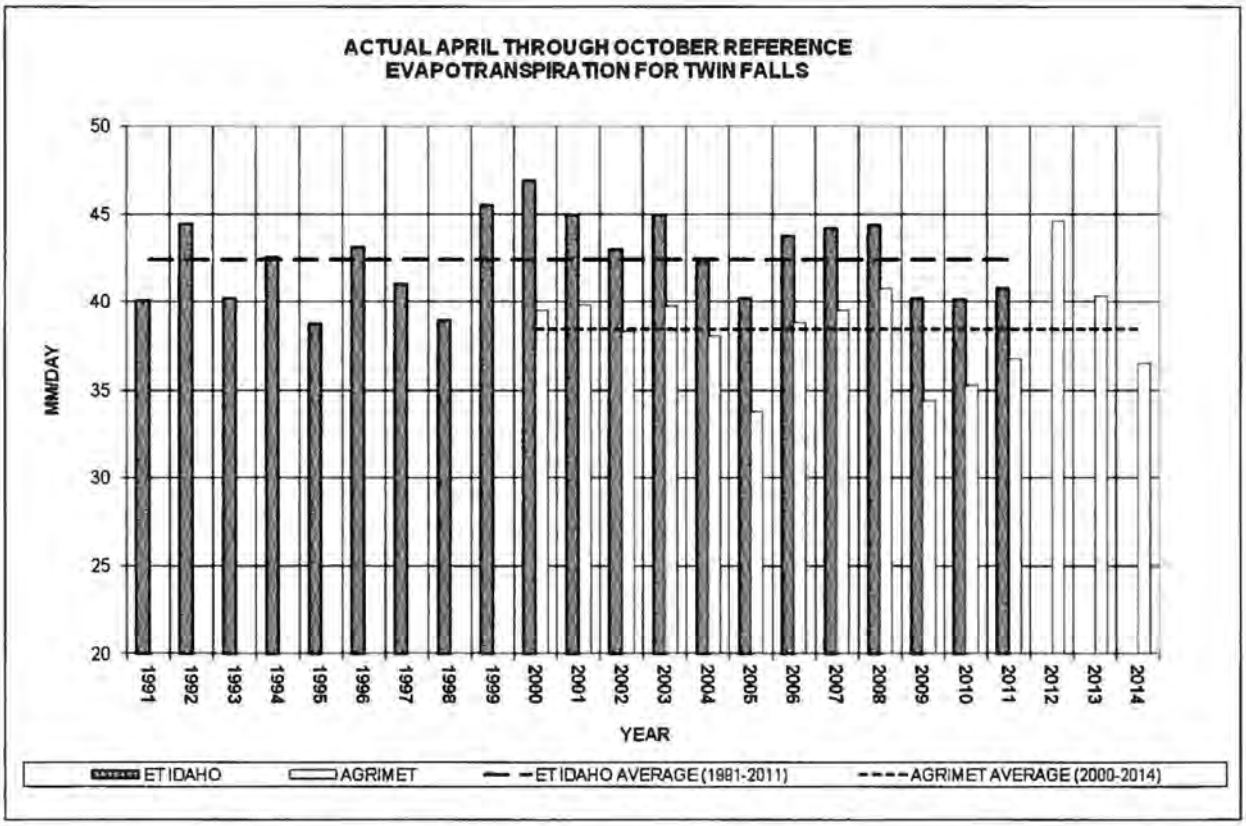
10. For the methods outlined herein, climate is represented by precipitation, ET, and growing degree days.

---

[3] All citations in this Order are to material that was admitted during the original hearing and is part of the final agency record on appeal in Gooding County Case No. CV-2008-551, which was lodged with the Fifth Judicial District Court on February 6, 2009.

11. Precipitation. Water, in all phases, introduced to Idaho from the atmosphere is termed precipitation. During the growing season, precipitation reduces the irrigation water needed for growing crops. Ex. 3024 at 19. The figure below shows the precipitation recorded during the growing season at the National Weather Service's Twin Falls weather station.

Growing Season Precipitation at National Weather Service's Twin Falls Weather Station 1990–2014.[4]



12. Evapotranspiration. ET is a variable representing both the amount of water that transpires from vegetation and the amount of water that evaporates from the underlying soil. ET is an important factor for properly estimating RISD. In its water budget calculations, the SWC proposed the use of ET values from the USBR as part of their Pacific Northwest Cooperative Agricultural Network, i.e. AgriMet. Ex. 8000, Vol. II, Chap. 9; Ex. 8000, Vol. IV, Appdx. AU. The ground water users proposed the use of ET values from Richard G. Allen and Clarence W. Robison 2007, Evapotranspiration and Consumptive Irrigation Water Requirements for Idaho, i.e. ETIdaho. Ex. 3007A at 21; Ex. 3024 at 1-58.

13. Reference ET is a standardized index that approximates the climatic demand for water vapor (i.e. ET). Both ETIdaho data and AgriMet data are Reference ET data sets. The Department will identify potential BLYs by consulting both ETIdaho Reference ET and AgriMet Reference ET.

[4] Chart created from raw NOAA National Weather Service total precipitation data obtained from the NCDC's Climatological Data Annual Summary Idaho report series for the Twin Falls 6 E and Twin Falls Sun Valley Regional Airport weather stations.

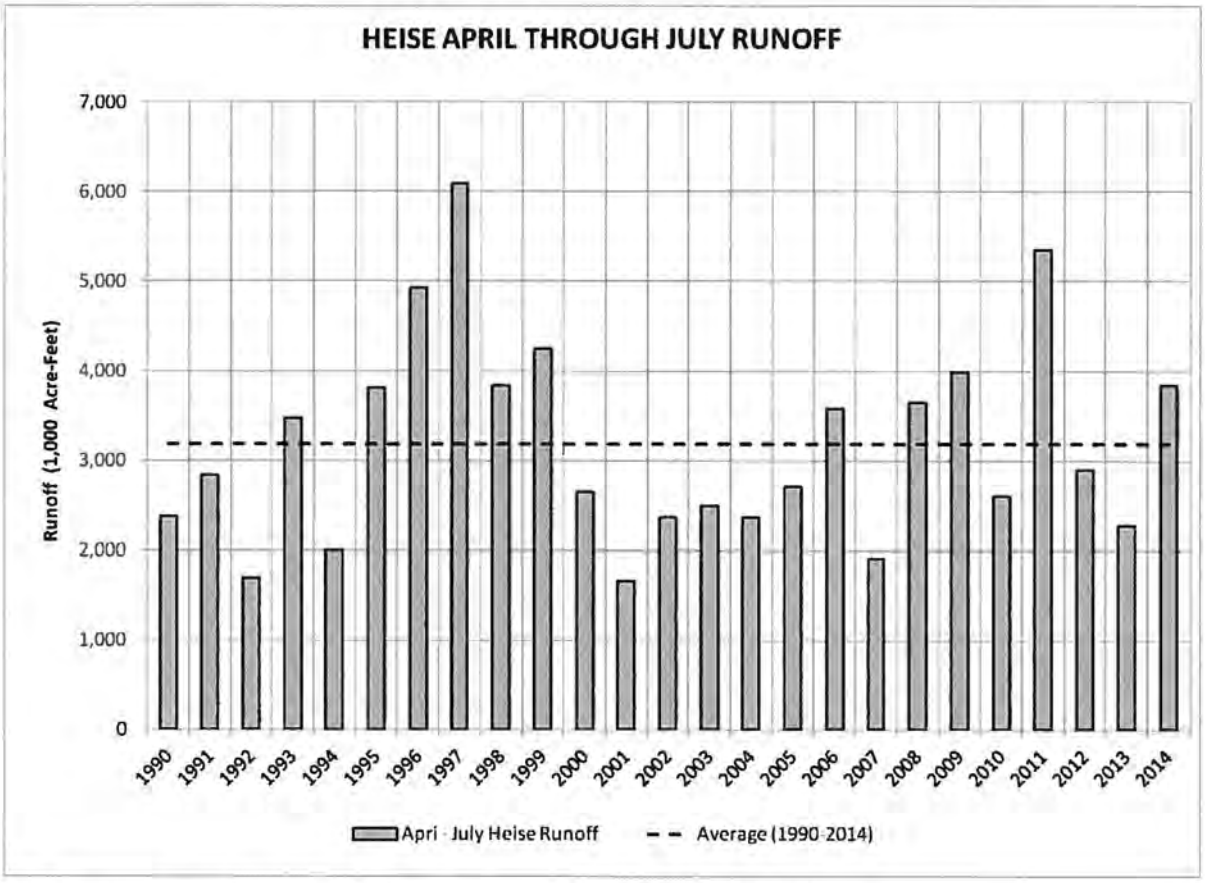
14. Neither ETIdaho Reference ET data nor AgriMet Reference ET data span the entire period of analysis (1990-2014). ETIdaho Reference ET data are currently available from 1990 through 2011. AgriMet Reference ET data are available from 2000 to 2014. Ideal BLY candidates are years in which Reference ET exceeds average Reference ET values. The individual year is compared using both AgriMet and ETIdaho Reference ET data for those years in which both data are available and only AgriMet data in those years where there is no ETIdaho data.

15. Years of above average values of Reference ET are appropriate BLY candidates.[5] Total April through October Reference ET for the period of record from the Twin Falls (Kimberly) AgriMet site is shown below.

Actual Reference ET for Twin Falls (Kimberly) with both AgriMet and ETIdaho data 1991-2014.

[5] Values for Reference ET between ETIdaho and AgriMet do not match because they are derived differently. The relevant information for identifying a potential BLY is the relationship between the year under consideration and the average for the data sets.

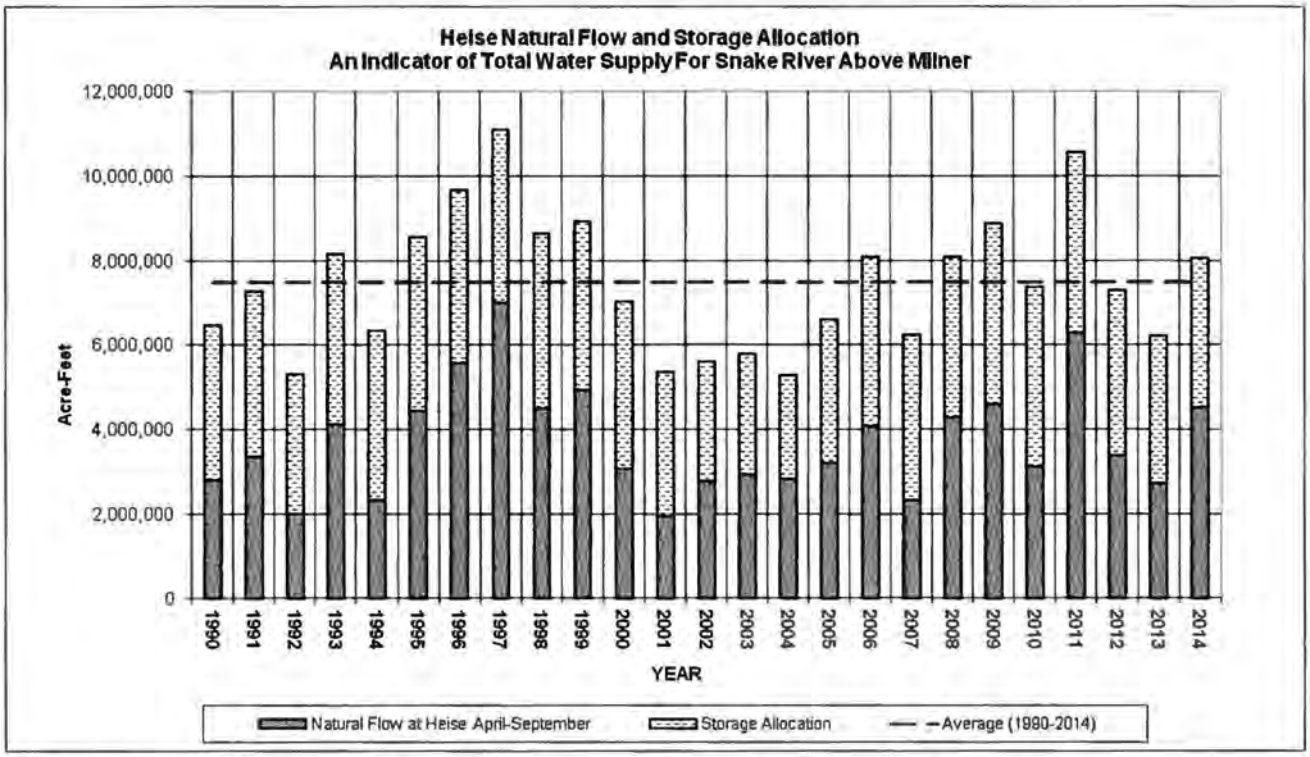
16. Growing Degree Days. Growing degree days define the length and type of growing season. Growing degree days are an arithmetic accumulation of daily mean temperature above a certain base temperature. Ex. 3024 at 10; 117-21. These growth units are a simple method of relating plant growth and development to air temperatures. Different plant species have different base temperatures below which they do not grow. At temperatures above this base, the amount of plant growth is approximately proportional to the amount of heat or temperature accumulated. A higher annual growing degree day value correlates to a higher potential rate of plant growth. The table below shows growing degree days accumulated for April through September for the Twin Falls (Kimberly) AgriMet site.



Year	GDD: April-Sept	% of Average	Year	GDD: April-Sept	% of Average
1991	2,095.4	86%	2003	2,585.4	106%
1992	2,610.7	107%	2004	2,428.9	99%
1993	2,004.7	82%	2005	2,320.1	95%
1994	2,516.8	103%	2006	2,601.9	106%
1995	2,257.8	92%	2007	2,657.7	109%
1996	2,418.6	99%	2008	2,382.9	97%
1997	2,478.4	101%	2009	2,469.7	101%
1998	2,422.2	99%	2010	2,215.0	91%
1999	2,294.9	94%	2011	2,314.6	95%
2000	2,591.3	106%	2012	2,735.3	112%
2001	2,600.8	106%	2013	2,672.8	109%
2002	2,465.6	101%	2014	2,553.0	104%

Average GDD (1991-2014): 2,445.6

Growing Degree Days ("GDD") for Twin Falls (Kimberly) AgriMet Site 1991-2014.



ii. Available Water Supply

17. The April through July Heise runoff volume represents the volume of water available for diversion into storage reservoirs and also is an indicator of natural flow supplies. The graph below shows actual unregulated flow volumes at Heise for 1990 through 2014. The 1990 to 2014 average (3,186,000 acre-feet) is displayed by the dashed line.

April through July Unregulated Flow Volume at Heise, 1990-2014.

18. The sum of the Heise natural flow and the reservoir storage allocations is an indicator of the total supply of the Snake River. The sum of the Heise natural flow and reservoir storage allocations for each year from 1990-2014 is represented in the graph below.

The sum of the Heise natural flow and the storage allocation for the Snake River above Milner 1990-2014.

iii. Irrigation Practices

19. A BLY must be recent enough to represent current irrigation practices. R. Vol. 37 at 7099-7100. Conditions that should be consistent are: (a) the net area of the irrigated crops, (b) farm application methods (flood/furrow or sprinkler irrigation), and (c) the conveyance system from the river to the farm. The type of sprinkler systems should be similar between the BLY and the current year.

20. Sprinkler systems are currently the predominant application system. *Id.* at 7101-02. To ensure that current irrigation practices are captured, selection of a BLY for the SWC should be limited to years subsequent to 1999. *Id.* at 7096; 7099-7100.

21. Estimates of irrigated acres from the hearing show a trend of decreasing irrigated acreage. R. Vol. 28, 5205-15; R. Vol. 37 at 7100. According to the Hearing Officer, beneficial use cannot occur on acres that have been hardened or are otherwise not irrigated. R. Vol. 37 at 7100.

22. There are lands within the service areas of SWC entities that are irrigated with supplemental groundwater. Exhibit 3007. Supplemental groundwater is a factor the Director can consider in the context of a delivery call. *Methodology Remand Order* at 18-19. At this time, the information submitted or available to the Department is insufficient to determine the extent of supplemental irrigation on lands within the service areas of SWC entities.

B. Selection of the Initial Baseline Year

23. The selection of a single BLY for all entities is challenging, with individual years satisfying some of the BLY requirements but not all. By selecting a BLY that is comprised of the average of multiple years, a BLY can be selected that better represents the required conditions for all entities. The years 2000-2014 were considered for the BLY selection. Finalized 2015 data were not available in sufficient time to be considered for BLY selection.

24. When selecting the BLY the Director must evaluate recent data to determine whether the standards of selection of a BLY are satisfied.

25. In the Second Methodology Order the Director used an average of 2006 and 2008 (06/08) for the BLY. The 06/08 BLY no longer satisfies the BLY selection criteria. In particular, when compared to the average of the annual diversions from 2000-2014, the 06/08 diversions are no longer above average.

26. The Director reviewed the years since issuance of the Second Methodology Order and finds that 2012 satisfies the selection criteria for a BLY. However, 2012 had the lowest growing season precipitation, highest ET, and most growing degree days during the BLY selection period (1991-2014). Because 2012 represents the maximum values for these criteria during the period of analysis, 2012 is not an appropriate single-year BLY candidate.

27. Individually no one year during the period of analysis satisfied all the BLY requirements; 2006 had below average diversions, 2008 had below average growing degree days, and 2012 had record high ET, record high growing degree days, and record low precipitation. The Director finds that using the values from 2006, 2008, and 2012 (06/08/12) for an average BLY fits the selection criteria. When compared to the period 1991-2014, the 06/08/12 average has below average growing season precipitation, above average ET, above average growing degree days, and represents years in which diversions were not limited by availability of water supply. The 06/08/12 average diversions are greater than the average of the combined annual diversions from 2000-2014.

	2000-2014 Avg. Diversions (Acre-Feet)	06/08/12 Avg. Total Diversions (Acre-Feet)	06/08/12 % of Avg.
A&B	57,906	59,993	104%
AFRD2	420,863	427,672	102%
BID	242,646	251,531	104%
Milner	50,430	47,135	94%
Minidoka	354,277	369,492	104%
NSCC	982,567	978,888	100%
TFCC	1,045,120	1,060,011	101%
			Average 101%

Average SWC Diversions (acre-feet) for 2000-2014 and 2006/2008/2012 BLY.

28. The sum of the Heise natural flow and the storage allocation is an indicator of total water supply. As depicted in Finding of Fact 18, the values for 2006 and 2008 were greater than the average value for 1990-2014, while the value for 2012 was slightly below the average. The average value for 06/08/12 is greater than the average value for 1990-2014. Because the 06/08/12 average value exceeds the 1990-2014 average value, the BLY is not a year in which diversions were limited by water supply.

C. Calculation of Reasonable In-Season Demand

29. RISD is the projected annual diversion volume for each SWC entity during the year of evaluation that is attributable to the beneficial use of growing crops within the service area of the entity. Given that climate and system operations for the year being evaluated will likely be different from the BLY, the BLY must be adjusted for those differences. As stated by the Hearing Officer, "The concept of a baseline is that it is adjustable as weather conditions or practices change, and that those adjustments will occur in an orderly, understood protocol." R. Vol. 37 at 7098.

i. Project Efficiency

30. Project efficiency ("E_p") is the ratio of total volumetric crop water need within a SWC entity's boundary and the total volume of water diverted by that entity to satisfy its crop needs. It is the same concept as system efficiency, which was presented at hearing. Ex. 3007 at 28-29. Implicit in this relationship are the components of seepage loss (conveyance loss), on-farm application losses (deep percolation, field runoff), and system operational losses (return flows) for which data is not obtainable by the Department. By utilizing project efficiency and its input parameters of crop water need and total diversions, the influence of the unknown components for which data is not obtainable can be captured and described without quantifying each of the components. Project efficiency is derived by dividing crop water need by total diversions as depicted in the algorithm below:

$$E_p = \frac{CWN}{Q_D}$$

Where:

E_p = project efficiency,
CWN = crop water need, and
Q_D = irrigation entity diversion of water specifically put to beneficial use for the growing of crops within the irrigation entity.

31. Monthly SWC entity diversions ("Q_D") will be obtained from Water District 01's diversion records. Ex. 8000, Vol. II, at 8-4, 8-5. Raw monthly diversion values will then be adjusted to remove any water diversions that can be identified to not directly support the beneficial use of crop development within the irrigation entity. Examples of adjustments include the removal of diversions associated with in-season recharge and diversion of irrigation water on the behalf of another irrigation entity. Adjustments are unique to each SWC member and each irrigation season and will be evaluated each year. Any natural flow or storage water deliveries to entities other than the SWC for purposes unrelated to the original right will not be included as a part of the SWC water supply or carryover volume. Water that is purchased or leased by a SWC member may become part of the shortfall obligation to the extent that member has been found to have been materially injured. *See e.g.* R. Vol. 38 at 7201, fn. 11 (Eighth Supplemental Order). Conversely, water supplied to private leases or to the rental pool by a SWC member will be included as a part of the SWC supply for that member because non-inclusion would unjustifiably increase the shortfall obligation.

32. Monthly project efficiencies will be computed for the entire irrigation season. Project efficiency varies from month-to-month during the season, and will typically be lower during the beginning and ending of the season. Monthly project efficiencies will be divided into actual monthly crop water need ("CWN") values to determine RISD during the year of evaluation. The table below presents average project efficiencies for each SWC member (2007-2014). Project efficiencies from 2007-2014 greater or less than two standard deviations from the average are excluded from the calculation. By including only those values within two standard deviations, extreme values from the data set are removed.

Month	A&B	AFRD2	BID	Milner	Minidoka	NSCC	TFCC	Monthly Avg.
4	1.67	0.39	0.43	0.77	0.47	0.16	0.30	0.60
5	0.61	0.29	0.28	0.41	0.37	0.29	0.31	0.37
6	0.73	0.43	0.44	0.63	0.54	0.47	0.51	0.54
7	0.68	0.45	0.56	0.74	0.61	0.50	0.58	0.59
8	0.50	0.39	0.60	0.66	0.53	0.32	0.44	0.49
9	0.41	0.26	0.48	0.56	0.44	0.21	0.26	0.38
10	0.14	0.26	0.14	0.15	0.14	0.05	0.04	0.13
Season Avg.	0.68	0.35	0.42	0.56	0.44	0.29	0.35	0.44

SWC Member Average Monthly Project Efficiencies from 2007-2014.

ii. Crop Water Need

33. CWN is the volume of irrigation water required for crop growth within a SWC entity boundary, such that crop growth is not limited by water availability. CWN only applies to crops irrigated with surface water. CWN is the difference between the fully realizable consumptive use associated with crop growth, or ET, and effective precipitation (W_e) and is synonymous with the terms irrigation water requirement and precipitation deficit. Ex. 3024. For the purposes of the methodology, CWN is calculated as set forth below:

$$CWN = \sum_{i=1}^{n} (ET_i - W_e) A_i$$

Where,

CWN = crop water need
ET_i = consumptive use of specific crop type,
W_e = effective precipitation,
A_i = total irrigated area of specific crop type,
i = index variable representing the different specific crop types grown within the irrigation entity, and
n = upper bound of summation equal to the total number of different specific crop types grown within the irrigation entity.

iii. Evapotranspiration

34. ET can be calculated with theoretically based equations that calculate ET for an individual crop, necessitating crop distribution maps for each year. Ex. 3007A at 21, Figure 3, Tables 6-12; Ex. 3024 at 1-58; Ex. 8000, Vol. II at Chapter 9; Ex. 8000, Vol. IV, Appdx. AU.

35. At hearing, values of ET were estimated by the SWC from AgriMet, Ex. 8000, Vol. IV, Appdx. AU-1, and by the ground water users from ETIdaho, Ex. 3007A at 21; Ex. 3024 at 1-58. At this time, the Director finds that the use of AgriMet is more appropriate for determining ET than ETIdaho because AgriMet is available to all parties in real-time without the need for advanced programming. Accordingly, the methodology will rely on AgriMet derived ET values in the calculations of project efficiency, CWN, and RISD. In the future, with the development of additional enhancements, ETIdaho may become a more appropriate analytical tool for determining ET.

36. CWN is derived by multiplying crop specific ET values, adjusted for estimated effective precipitation, by the total irrigated area of individual crop types, and summing for all crop types. The areas for individual crop types will be derived from published crop distributions from the United States Department of Agriculture's National Agricultural Statistics Service ("NASS"). Ex. 1005 at 1. NASS annually creates a crop-specific land cover digital dataset from satellite imagery and field checks. The dataset is called the Cropland Data Layer (CDL). Each year, the Department will calculate acreage by crop type for each SWC entity using NASS CDL data. In the future, the NASS data may not be the most accurate source of data. The Department prefers to rely on data from the current season if and when it becomes usable.

37. AgriMet ET and precipitation data are gathered at the Rupert and Twin Falls (Kimberly) stations. Both stations are located in the vicinity of the SWC entities. A&B Irrigation District ("A&B"), Burley Irrigation District ("BID"), and Minidoka Irrigation District ("Minidoka") are nearest to the Rupert AgriMet station. ET data gathered at the Rupert station reasonably represents the climate conditions for A&B, BID, and Minidoka. American Falls Reservoir District No. 2 ("AFRD2"), Milner Irrigation District ("Milner"), North Side Canal Company ("NSCC"), and Twin Falls Canal Company ("TFCC") are nearest to the Twin Falls (Kimberly) AgriMet station. ET data gathered at the Twin Falls (Kimberly) station reasonably represents the climate conditions for AFRD2, Milner, NSCC, and TFCC. Ex. 8000, Vol. IV at AU-2, AU-8.

iv. Effective Precipitation

38. Effective precipitation ("W_e") is the amount of total precipitation held in the soil horizon available for crop root uptake. Effective precipitation will be estimated from total precipitation (W) employing the methodology presented in the USDA Technical Bulletin 1275. Ex. 8000, Vol. IV, Appdx. AU3, AU8. Total precipitation (W) data is published by the USBR as part of its Pacific Northwest Cooperative Agricultural Network, i.e. AgriMet. Ex. 8000, Vol. IV, Appdx. AU3. W_e values derived from AgriMet based precipitation values are independent of crop type.

39. AgriMet precipitation (W) values are easy to understand and regularly used by the farming, water supply, and water management communities. Accordingly, the methodology will rely on AgriMet derived W values in the calculations of CWN and RISD.

40. As with ET data, AgriMet precipitation data are available from the Rupert and Twin Falls (Kimberly) stations. AgriMet data from the Rupert station reasonably represents climate conditions for A&B, BID, and Minidoka. AgriMet data from Twin Falls (Kimberly) reasonably represents climate conditions for AFRD2, Milner, NSCC, and TFCC. Ex. 8000, Vol. IV at AU-2, AU-8.

v. Summary of Reasonable In-Season Demand Calculation

41. At the start of the irrigation season, RISD is equal to the BD, or total season adjusted diversions for the BLY. When calculated in-season, RISD is calculated below.

$$RISD_{milestonex_x} = \sum_{j=1}^{m}\left(\frac{CWN_j}{E_{p,j}}\right) + \sum_{j=m+1}^{7} BD_j$$

Where:

$RISD_{milestone_x}$ = reasonable in season demand at specified evaluation milestones during the irrigation season,
CWN = crop water need for month j,
E_p = baseline project efficiency for month j,
BD = baseline demand for month j,
j = index variable, and
m = upper bound of summation, equal to the month calculation occurs, where April = 1, May =2, … October = 7.

42. April RISD Adjustment: In April, the calculated RISD, which is the quotient of CWN and Ep, can under estimate actual canal operation diversions. This occurs when the actual CWN value for April is much smaller than the diversion of water into the canal system necessary to effectively operate the irrigation delivery system. Often, CWN in April is small due to precipitation, cool temperatures, and/or the immaturity of the crop. The diversion rate at the head gate necessary to push water into all laterals and field head gates throughout the delivery system often dwarfs the water necessary to strictly satisfy CWN. In addition, it is difficult for canal systems to be dynamically operated to match the frequent precipitation events that occur in April, which also contributes to a diversion of water at the canal head gate that exceeds the diversion of water necessary to strictly satisfy CWN. To account for the conditions affecting the usability of the calculated RISD value for April, the values may be adjusted for each individual irrigation delivery entity in the SWC as described below.

43. When the calculation of CWN/Ep results in a value for the month of April less than the average April diversion volume over a record of representative years in the recent past, the April RISD is set equal to the average April diversion volume. When the calculation of CWN/Ep results in a value greater than the average April diversion volume, the April RISD is equal to the calculated CWN/Ep volume.

44. October RISD Adjustment: In October, the calculated RISD, which is the quotient of CWN and Ep, can both under estimate and over estimate actual canal operation diversions. The RISD may be underestimated when the actual CWN value for October is much smaller than the diversion of water into the canal system necessary to effectively operate the irrigation delivery system. The diversion rate at the head gate necessary to push water into all laterals and field head gates throughout the delivery system often dwarfs the water necessary to strictly satisfy CWN. In addition, it is difficult for canal systems to be dynamically operated to match the frequent precipitation events that occur in October, which also contributes to a diversion of water at the canal head gate that exceeds the diversion of water necessary to strictly satisfy CWN. Furthermore, RISD may be under-estimated in October when a farmer diverts water at the field head gate for farming practices other than strictly satisfying CWN. Examples of water diversion practices at the field head gate that sometimes occur in October include diverting water for soil salt leaching, diverting water to build up the soil moisture profile for the following irrigation season, and/or diverting water to wet-up bare soil to prevent wind-driven top soil erosion.

45. Unlike the month of April, RISD can be over-estimated in October. RISD may be over-estimated in years when actual CWN in October is much greater than typical CWN over a record of representative years in the recent past due to low precipitation and/or warm temperatures. To account for the conditions affecting the usability of the RISD value calculated for October, the values may be adjusted for each individual irrigation delivery entity in the SWC as described below.

46. When the calculation of CWN/Ep results in a value for the month of October greater than the maximum October diversion volume from a record of recent representative years, or less than the minimum October diversion volume from the same record of recent representative years, the October RISD is set equal to the average October diversion volume over the same period of recent representative years. When the calculation of CWN/Ep results in a value between the maximum and minimum October diversion volumes from a record of recent representative years, the October RISD is equal to the calculated CWN/Ep volume.

D. Adjustment of Forecast Supply

47. As stated by the Hearing Officer, "There must be adjustments as conditions develop if any baseline supply concept is to be used." R. Vol. 37 at 7093.

i. April Forecast Supply

48. The FS is comprised of natural flow and stored water.

49. Typically within the first week of April, the USBR and the USACE issue their Joint Forecast that predicts an unregulated inflow volume at the Heise Gage from April 1 to July 31 for the forthcoming year. The joint forecast ("Joint Forecast") issued by the United States Bureau of Reclamation ("USBR") and the United States Army Corp of Engineers ("USACE") for the period April 1 through July 31 "is generally as accurate a forecast as is possible using current data gathering and forecasting techniques." R. Vol. 8 at 1379, ¶ 98. Given current

forecasting techniques, the earliest the Director can predict material injury "with reasonable certainty" is soon after the Joint Forecast is issued. R. Vol. 2 at 226. With data from 1990 through the irrigation year previous to the current year, a regression equation will be developed for each SWC member. The regression equations for A&B and Milner were developed by comparing the actual Heise natural flow to the natural flow diverted. *See e.g.* R. Vol. 8 at 1416-22. For AFRD2, BID, Minidoka, NSCC, and TFCC, multi-linear regression equations were developed by comparing the actual Snake River near Heise natural flow and the flows at Box Canyon to the natural flow diverted. The regression equations will be used to predict the natural flow diverted for the upcoming irrigation season. *Id.* at 1380. The actual natural flow volume predicted in the Director's April FS for each SWC entity will be one standard error below the regression line, which underestimates the available supply. *Id.*; Tr. p. 65, lns. 6-25; p. 66, lns. 1-2. The purpose of the shift to one standard error below the regression line is to ensure senior water right holders do not bear the risk of under-prediction of supply. The forecasting techniques will be revised based on updated data and the forecasting techniques may be revised when improvements to the forecasting tools occur.

50. The storage allocation for each member of the SWC will be estimated by the Department following issuance of the Joint Forecast. The Department will forecast reservoir fill and storage allocation consistent with the methods established in the *Fifth Supplemental Order Amending Replacement Water Requirements Final 2006 & Estimated 2007.* R. Vol. 23 at 4294-97 as explained below. The Department will evaluate the current reservoir conditions and the current water supply outlook to determine a historical analogous year or years to predict reservoir fill. The Department may identify and use a combination of different analogous years to predict individual reservoir fill. Input variables for determining the individual storage water allocation for each SWC member are: (a) the analogous year's or years' total reservoir fill volume; (b) an estimated evaporation volume; and (c) the previous year's carryover volume. The FS (the combination of the forecast of natural flow supply and the storage allocation) for each SWC member will be determined by the Director shortly after the date of the Joint Forecast.

51. If, at any time prior to the Director's final determination of the April FS, the Director can determine with certainty that any member of the SWC has diverted more natural flow than predicted, or has accrued more storage than predicted, the Director will revise his initial, projected shortfall determination.

ii. July Forecast Supply

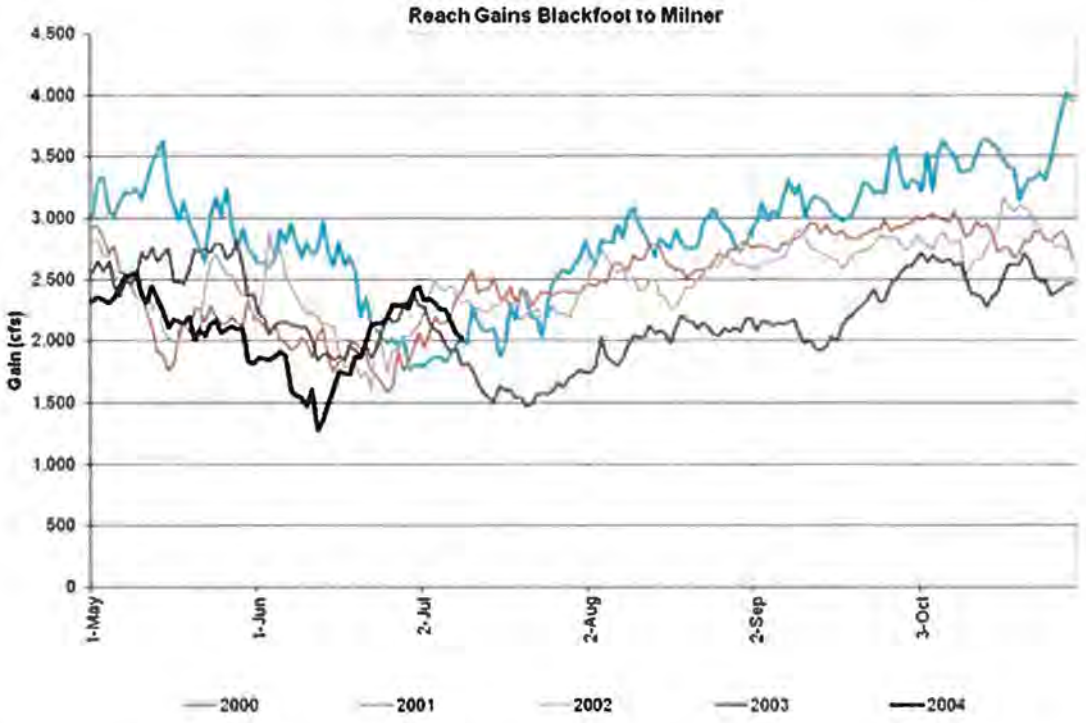
52. Approximately halfway through the irrigation season, the FS will be adjusted. When adjusting the natural flow component of the FS, the Department's water rights accounting program will compute the year-to-date natural flow diverted by each member of the SWC. The natural flow diversion for the remainder of the irrigation season will be estimated based on the regression analyses.

53. The natural flow supplies for each SWC member are comprised of natural flow in the Snake River passing the near Blackfoot gage and gains which occur in the Snake River between the Blackfoot to Milner reach. Many different predictor variables were considered when developing the models used to predict the natural flow supplies for the remainder of the

season, including those variables used in the April FS. A step-wise statistical analysis was employed to help select the variables for each model. The following variables were selected to forecast water supplies halfway through the irrigation season: natural flow in the Snake River near Heise as reported by the U.S. Bureau of Reclamation; snow water equivalent (SWE) data at the Two Oceans Plateau SNOTEL site; Spring Creek discharge; and groundwater levels near American Falls Reservoir. The model predictors were optimized for each SWC member and are summarized in the sections below.

54. Linear regression equations for AFRD2, A&B, and Milner, were developed by comparing the July 1 snow water equivalent (inches) at the Two Oceans Plateau SNOTEL site to the natural flow diversions. The regression equations for AFRD2, A&B, and Milner would be applied only in those years when the snow water equivalent at the Two Oceans Plateau SNOTEL site is greater than zero (0). Years when the snow water equivalent equals zero, the total natural flow prediction for the period July 1 to October 31 will be zero (0) AF.

55. Multiple linear regression equations for BID, Minidoka, and NSCC were developed to predict natural flow diversions employing the following predictor variables: (1) Snake River near Heise natural flow (April – June), (2) March depth to water at well 05S2E27ABA1 and (3) the snow water equivalent at the Two Oceans Plateau SNOTEL site on June 15.



56. The multiple linear regression model for TFCC will be based on the following predictor variables: (1) Snake River near Heise natural flow (April – June), (2) Spring Creek total discharge (January – May) and (3) the snow water equivalent at the Two Oceans Plateau SNOTEL site on June 15.

57. When adjusting the storage component of the FS, the Department must consider whether stored water has been allocated. In normal to dry years, the reservoirs will typically have filled to their peak capacity for the season and the storage water will have been allocated. If the BOR and Water District 01 have allocated stored water to spaceholders, the Department will use the actual preliminary storage allocations to the SWC. If the BOR and Water District 01 have not yet allocated stored water to spaceholders, the Department will predict the storage allocations based on the storage allocations from an analogous year.

iii. Time of Need

58. The FS will again be adjusted shortly before the Time of Need. The Time of Need is established by predicting the day in which the remaining storage allocation will be equal to reasonable carryover. The Time of Need will not be earlier than the Day of Allocation.

59. When adjusting the natural flow component of the FS, the Department's water rights accounting program will compute the natural flow diverted by each member of the SWC as of the new forecast date. The natural flow diversion for the remainder of the irrigation season will be estimated based on a historical year with similar reach gains in the Blackfoot to Milner reach. The following is an example of estimating reach gains from an analysis of historical years. Reach gains for the years 2000 – 2003 and a portion of year 2004 are graphed below. Considering 2004 as an example of a current year, and comparing 2004 to the hydrographs for 2000 – 2003, year 2003 has similar reach gains and is appropriately conservative. Therefore, the natural flow diverted in 2003 would be used to predict the natural flow diversions for the remainder of the 2004 season.

Example Reach Gain Analysis for 2004.

60. When adjusting the storage component of the FS, the Department will use the actual preliminary storage allocations to the SWC.

61. The adjusted FS is the sum of the year-to-date natural flow diversions, the predicted natural flow diversions for the remainder of the season, and the storage allocation.

E. Calculation of Demand Shortfall

62. The equation below determines the amount of predicted demand shortfall during the irrigation season.

$$DS = FS - RISD$$

Where:

DS = demand shortfall for specified evaluation points throughout the season,
FS = forecasted supply for remainder of season after specified evaluation point during the season, and
RISD = Reasonable in-season demand from above.

63. The amount calculated represents the volume that junior ground water users with approved mitigation plans for delivery of water will be required to have available for delivery to members of the SWC found to be materially injured by the Director to avoid curtailment. The amounts will be calculated in April, at the middle of the season, and at the Time of Need.

III. Methodology for Determining Material Injury to Reasonable Carryover

64. Conjunctive Management ("CM") Rule 42.01.g states the following guidance for determining reasonable carryover: "In determining a reasonable amount of carry-over storage water, the Director shall consider average annual rate of fill of storage reservoirs and the average annual carry-over for prior comparable water conditions and the projected water supply for the system." Carryover shortfall will be determined following the completion of the irrigation season.

A. Projected Water Supply

65. CM Rule 42.01.g states that the Director "shall consider . . . the projected water supply for the system." Because it is not possible to adequately forecast the irrigation supply or demand for the following irrigation season at the end of the current irrigation season, the Director must estimate the carryover water needed in future dry years when demand exceeds supply, creating a need for carryover storage. The Director projected the water supply using typical dry years and subtracted it from a projected future demand to determine a projected carryover need.

66. The Heise natural flow is a predictive indicator of total water supply. For the years 2002 and 2004 the Heise natural flows were well below the long term average (1991-2014), but were not the lowest years on record. The average of the 2002 and 2004 supply will be the projected supply, representing a typical dry year. The 2002 and 2004 supply is computed as follows:

- 2002 supply = natural flow diverted + new storage fill
- 2004 supply = natural flow diverted + new storage fill
- Projected supply = average of 2002 supply and 2004 supply

Carryover from previous years is not included in the 2002 and 2004 new storage fill because it was not new water supplied during the 2002 or 2004 irrigation year.

	2002 Natural Flow Diverted	2002 New Storage Fill	2002 Total Supply	2004 Natural Flow Diverted	2004 New Storage Fill	2004 Total Supply	Projected Supply (Average 02/04)
	----------Acre-Feet----------						
A&B	853	45,603	46,456	1	36,535	36,536	41,496
AFRD2	25,749	381,451	407,200	4,562	309,698	314,260	360,730
BID	89,886	174,454	264,340	102,706	152,387	255,093	259,716
Milner	5,058	43,430	48,488	1,027	35,175	36,202	42,345
Minidoka	143,937	256,602	400,539	141,460	229,574	371,034	385,787
NSCC	363,960	667,799	1,031,759	315,942	479,068	795,010	913,385
TFCC	851,970	186,233	1,038,203	881,345	150,218	1,031,563	1,034,883

SWC water supplies 2002, 2004, and 2002/2004 average (acre-feet).

67. Similar to projecting supply, the Director must also project demand. Because it is not possible to adequately forecast the irrigation demand for the following irrigation season at the end of the current irrigation season, the Director must project demand. R. Vol. 37 at 7109. The average of 2006/2008/2012 BLY will be the projected demand.

68. The projected carryover need is defined as the difference between a BLY demand and projected typical dry year supply. The following equation computes the projected carryover need:

Projected Carryover Need = Projected Demand (06/08/12 BLY) – Projected Supply (Average 02/04)

	Projected Demand (06/08/12 BLY)	Projected Supply (Average 02/04)	Projected Carryover Need
	----------Acre-Feet----------		
A&B	59,992	41,496	18,496
AFRD2	427,672	360,730	66,942
BID	251,531	259,716	0
Milner	47,135	42,345	4,790
Minidoka	369,492	385,787	0
NSCC	978,888	913,385	65,503
TFCC	1,060,011	1,034,883	25,128

SWC Projected Demand, Projected Supply and Projected Carryover Need (acre-feet).

B. Average Annual Rate of Fill

69. CM Rule 42.01.g states that the Director "shall consider the average annual rate of fill of storage reservoirs . . . ." The average annual rate of fill of the storage reservoirs is the average of annual percentages of fill of each entity's reservoir space. The average annual reservoir fill is a benchmark that can be compared to projected carryover need. For purposes of the table below, any water contributed to the rental pool from the previous year was added to the next year's fill volume so that it does not artificially lower the percent fill. R. Vol. 37 at 7108. Water that is supplied to the rental pool lowers carryover and could impact the following year's fill. The percent fill does not include water deducted for reservoir evaporation. The annual percent fill of storage volume by SWC entity is shown below:

	A&B	AFRD2	BID	Milner	Minidoka	NSCC	TFCC
1995	100%	100%	100%	100%	100%	100%	100%
1996	100%	100%	100%	100%	100%	100%	100%
1997	100%	100%	100%	100%	100%	100%	100%
1998	100%	100%	100%	100%	100%	100%	100%
1999	100%	100%	100%	96%	100%	98%	99%
2000	100%	99%	99%	98%	100%	97%	97%
2001	100%	100%	100%	100%	100%	91%	87%
2002	41%	100%	100%	90%	92%	84%	88%
2003	43%	100%	99%	66%	92%	94%	99%
2004	34%	82%	98%	48%	95%	82%	63%
2005	58%	100%	100%	77%	98%	100%	100%
2006	98%	100%	99%	98%	100%	99%	99%
2007	89%	100%	83%	92%	77%	95%	97%
2008	100%	100%	85%	100%	80%	99%	100%
2009	100%	100%	100%	100%	100%	100%	100%
2010	100%	100%	100%	100%	100%	100%	100%
2011	100%	100%	100%	100%	100%	100%	100%
2012	88%	100%	97%	91%	94%	94%	96%
2013	80%	100%	97%	90%	86%	97%	100%
2014	93%	100%	100%	100%	93%	100%	100%
Average	87%	99%	99%	92%	96%	96%	96%
Std Dev	22%	4%	2%	14%	4%	6%	8%

Annual Percent Fill of Storage Volume by Entity (1995-2014).[6]

[6] *See e.g.* Ex. 4125. Exhibit 4125 accounts for water deducted for evaporation, but does not take into account water supplied to the rental pool.

C. Average Annual Carryover

70. CM Rule 42.01.g states that the Director "shall consider the . . . average annual carry-over for prior comparable water conditions . . . ." Actual carryover volumes were adjusted from values reported in the storage reports so that they did not include water received for mitigation purposes or water rental by the canal company for use within the irrigation district. R. Vol. 37 at 7108. Actual carryover from 1995 through 2014 was sorted into categories ranging from very dry to wet. The categories are based on the Heise natural flow volumes from April through September.

Heise April - Sept. Natural Flow (1000's Acre-Feet)	Year	Heise Natural Flow April – Sept (1000's Acre-Feet)	A&B	AFRD2	BID	Milner	Minidoka	NSCC	TFCC
						Acre-Feet			
Very Dry	2001	1,968	9,902	4,217	37,430	26,854	55,132	42,421	26,917

	Avg.	**5,502**	**92,011**	**141,806**	**137,251**	**65,152**	**224,206**	**470,655**	**136,751**

Actual Carryover Volumes by Entity, Sorted by Heise Natural Flow (1995-2014).

71. In considering the principles articulated in CM Rule 42.01.g, the Director will project reasonable carryover shortfalls for members of the SWC. The following table represents the 2006/2008/2012 BLY diversion volumes and total reservoir storage space by entity. By dividing the total reservoir space by the 2006/2008/2012 diversion volume, a metric is established that describes the total number of seasons the entity's reservoir space can supply water.

	A&B	AFRD2	BID	Milner	Minidoka	NSCC	TFCC
	----------Acre-Feet----------						
06/08/12 BLY	59,993	427,672	251,531	47,135	369,492	978,888	1,060,011
Total Reservoir Space	137,626	393,550	226,487	90,591	366,554	859,898	245,930
Number of Seasons of Reservoir Space	2.3	0.9	0.9	1.9	1.0	0.9	0.2

Total Reservoir Space[7] in Comparison to Demand.

D. Reasonable Carryover

i. A&B

72. A&B's reservoir space has the lowest average annual rate of fill with the highest variability in fill. *See* Finding of Fact 69. In very dry years, the potential exists that A&B's actual carryover will be less than the projected carryover need. *See* Finding of Fact 68 & 70. A&B has an approximate two-year water supply provided by its total available storage space. *See* Finding of Fact 71. Because of its lower rate of fill, it is likely A&B will experience carryover shortfalls in consecutive dry years. Because of these factors, the projected carryover need of 18,500 AF is the reasonable carryover for A&B. *See* Finding of Fact 78.

ii. AFRD2

73. AFRD2 has the highest and most consistent reservoir rate of fill of any member of the SWC. *See* Finding of Fact 69. Therefore, any unfilled space in the fall will most likely fill. AFRD2 has an approximate one-year supply available in storage. *See* Finding of Fact 71. In a very dry year, AFRD2's historical carryover volume is often less than the projected carryover need using the equation set forth in Finding of Fact 68 & 70. Given the high likelihood of filling during a multi-year drought and after a very dry year, the reasonable carryover can be adjusted downward from the calculated projected carryover need without shifting the risk of shortage to the senior right holder. Because of these factors, the historical average carryover in very dry years of 11,500 AF is the reasonable carryover for AFRD2. *See* Finding of Fact 78.

[7] *See* R. Vol. 8 at 1373-74.

iii. BID & Minidoka

74. In an average demand year, BID and Minidoka will have enough water to meet demands given a low water supply. *See* Finding of Fact 70. *See also* R. Vol. 37 at 7105. Historically, even in very dry years, BID's and Minidoka's carryover have been well above the projected carryover need and it is unlikely that they will have reasonable carryover shortfalls in the future. *See* Finding of Fact 68 & 70. *See also* R. Vol. 37 at 7105. Because of these factors, the projected carryover need of 0 AF is the reasonable carryover for BID and Minidoka. *See* Finding of Fact 78. *See also* R. Vol. 37 at 7105.

iv. Milner

75. Similar to A&B, Milner's reservoir space has the second lowest average annual rate of fill of all entities with a high degree of variability in fill. *See* Finding of Fact 69. In very dry years, the potential exists that Milner's actual carryover will be less than the projected carryover need. *See* Finding of Fact 68 & 70. Milner has an approximate two-year water supply available in storage. *See* Finding of Fact 71. Because of its rate of fill, it is likely Milner will experience carryover shortfalls in consecutive dry years. Because of these factors, the projected carryover need of 4,800 AF is the reasonable carryover for Milner. *See* Finding of Fact 78.

v. NSCC

76. NSCC has a near average annual rate of fill in comparison to all entities and an approximate one-year water supply available in storage. *See* Findings of Fact 69 & 71. In dry years, the potential exists that its projected carryover need will be less than its actual carryover. *See* Finding of Fact 68 & 70. Because of these factors, the projected carryover need of 65,500 AF is the reasonable carryover for NSCC. *See* Finding of Fact 78.

vi. TFCC

77. TFCC has a near average annual rate of fill in comparison to all entities, but only a one-quarter of a year's water supply available in storage. *See* Findings of Fact 69 & 71. In dry years, the potential exists that its projected carryover need will be less than its actual carryover. *See* Finding of Fact 68 & 70. Because of these factors, the projected carryover need of 25,200 AF is the reasonable carryover for TFCC. *See* Finding of Fact 78.

78. Reasonable carryover values for the SWC members are as follows:

	Reasonable Carryover (Acre-Feet)
A&B	18,500
AFRD2	11,500
BID	0
Milner	4,800
Minidoka	0
NSCC	65,500
TFCC	25,200

E. Reasonable Carryover Shortfall

79. Reasonable carryover shortfall is the numerical difference between reasonable carryover and actual carryover, calculated at the conclusion of the irrigation season. Actual carryover is defined as the storage allocation minus the total storage use plus or minus any adjustments. Examples of adjustments include SWC water placed in the rental pool and SWC private leases. Adjustments are unique to each irrigation season and will be evaluated each year. Any storage water deliveries to entities other than the SWC for purposes unrelated to the original right will be adjusted so that the water is not included as a part of the SWC carryover volume. Water that is purchased or leased by an SWC member may become part of the carryover shortfall obligation. *See e.g.* R. Vol. 38 at 7201, fn. 11 (Eighth Supplemental Order). Conversely, actual carryover must be adjusted to assure that water supplied by a SWC member to private leases or to the rental pool will not increase the reasonable carryover shortfall obligation to the same SWC member.

80. Reasonable carryover shortfall is calculated as follows:

Reasonable Carryover Shortfall = Actual Carryover – Reasonable Carryover

CONCLUSIONS OF LAW

1. This order contains the methodology by which the Director will determine material injury to RISD and reasonable carryover to members of the SWC.

2. "The agency's experience, technical competence, and specialized knowledge may be utilized in the evaluation of the evidence." Idaho Code § 67-5251(5); IDAPA 37.01.01.600.

3. Idaho Code § 42-602 states that, "The director of the department of water resources shall have discretion and control of the distribution of water from all natural sources . . . . The director of the department of water resources shall distribute water . . . in accordance with

the prior appropriation doctrine." According to the Hearing Officer, "It is clear that the Legislature did not intend to grant the Director broad powers to do whatever the Director might think right. However, it is clear also that the Legislature [in Idaho Code § 42-602] did not intend to sum up water law in a single sentence of the Director's authority." R. Vol. 37 at 7085. "Given the nature of the decisions which must be made in determining how to respond to a delivery call, there must be some exercise of discretion by the Director." *American Falls Res. Dist. No. 2 v. Idaho Dept. Water Resources*, 143 Idaho 862, 875, 154 P.3d 433, 446 (2007).

4. "The prior appropriation doctrine is comprised of two bedrock principles—that the first appropriator in time is the first in right and that water must be placed to a beneficial use." *In Matter of Distribution of Water to Various Water Rights Held by or for the Benefit of A & B Irrigation Dist.*, 155 Idaho 640, 650, 315 P.3d 828, 838 (2012). "The concept that beneficial use acts as a measure and limit upon the extent of a water right is a consistent theme in Idaho water law." *Id.*; *American Falls*, 143 Idaho at 879, 154 P.3d at 450 (stating that while an appropriation for a beneficial use is "a valuable right entitled to protection . . . . Nevertheless, that property right is still subject to other requirements of the prior appropriation doctrine."); *In re Water to Water Right Nos. 36-02551 & 36-07694 (Rangen, Inc.) IDWR Docket CM-DC-2011-004* at *18, Nos. 42775/42836, 2016 WL 1130276 (Idaho Mar. 23, 2016) (explaining the "policy of beneficial use" serves as a "limit on the prior appropriation doctrine."). [8]

5. "Concurrent with the right to use water in Idaho 'first in time,' is the obligation to put that water to beneficial use." *American Falls*, 143 Idaho at 880, 154 P.3d at 451; *see In re Distribution of Water to Various Water Rights Held by or for the Ben. of A&B Irr. Dist.*, 155 Idaho at 652, 315 P.3d at 840 (referring to "'the constitutional requirement that priority over water be extended only to those using the water'") (quoting *American Falls*, 143 Idaho at 876, 154 P.3d at 447). "'It is the settled law of this state that no person can, by virtue of a prior appropriation, claim or hold more water than is necessary for the purpose of the appropriation, and the amount of water necessary for the purpose of irrigation of the lands in question and the condition of the land to be irrigated should be taken into account.'" *In re Distribution of Water to Various Water Rights Held by or for the Ben. of A&B Irr. Dist.*, 155 Idaho at 650, 315 P.3d at 838 (quoting *Washington State Sugar v. Goodrich*, 27 Idaho 26, 44, 147 P. 1073, 1079 (1915)).

6. "[T]he policy of securing the maximum use and benefit, and least wasteful use of Idaho's water resources, has long been the policy in Idaho." *In re Water to Water Right Nos. 36-02551 & 36-07694 (Rangen, Inc.) IDWR Docket CM-DC-2011-004* at * 18 (citing *Clear Springs Foods, Inc. v. Spackman*, 150 Idaho 790, 808, 252 P.3d 71, 89 (2011)). The Idaho Constitution enunciates a policy of promoting "optimum development of water resources in the public interest." Idaho Const. Art. XV, § 7; *Baker v. Ore-Ida Foods, Inc.*, 95 Idaho 575, 584, 513 P.2d 627, 636 (1973). "There is no difference between securing the maximum use and benefit and least wasteful use of this State's water resources and the optimum development of water resources in the public interest. Likewise, there is no material difference between 'full economic development' and the 'optimum development of water resources in the public interest.' They are two sides of the same coin. Full economic development is the result of the optimum development of water resources in the public interest." *Clear Springs*, 150 Idaho at 809, 252

[8] As of the date of this Fourth Methodology Order, the Idaho Supreme Court has not issued a remittitur in *In re Water to Water Right Nos. 36-02551 & 36-07694 (Rangen, Inc.) IDWR Docket CM-DC-2011-004.*

P.3d at 90. "The policy of securing the maximum use and benefit, and least wasteful use, of the State's water resources applies to both surface and ground waters, and it requires that they be managed conjunctively." *Id.*

7. "Conjunctive administration 'requires knowledge by the [Department] of the relative priorities of the ground and surface water rights, how the various ground and surface water sources are interconnected, and how, when, where and to what extent the diversion and use of water from one source impacts the water flows in that source and other sources.' . . . . That is precisely the reason for the CM Rules and the need for analysis and administration by the Director." *American Falls,* 143 Idaho at 877, 154 P.3d at 448.

8. The CM Rules incorporate all principles of the prior appropriation doctrine as established by Idaho law. *American Falls*, 143 Idaho at 873, 154 P.3d at 444; CM Rule 20.02, 10.12.

9. While the presumption under Idaho law is that an appropriator is entitled to his decreed water right and the CM Rules may not be applied so as to require a senior appropriator to demonstrate an entitlement to the water in the first place, there may be post-adjudication factors relevant to the determination of how much water is actually needed in responding to a delivery call. *American Falls*, 143 Idaho at 877-78, 154 P.3d at 448-49. Under the CM Rules and Idaho law, the Director has the "authority and responsibility to investigate claims when delivery calls are made," and the "authority to evaluate the issue of beneficial use in the administration context." *In re Distribution of Water to Various Water Rights Held by or for the Ben. of A&B Irr. Dist.*, 155 Idaho at 652, 315 P.3d at 840. As the Idaho Supreme Court recently stated, "'[w]hile the prior appropriation doctrine certainly gives pre-eminent rights to those who put water to beneficial use first in time, this is not an absolute rule without exception . . . the Idaho Constitution and statutes do not permit waste and require water to be put to beneficial use or be lost.'" *In re Water to Water Right Nos. 36-02551 & 36-07694 (Rangen, Inc.) IDWR Docket CM-DC-2011-004* at *17 (quoting *American Falls*, 143 Idaho at 880, 154 P.3d at 433). "[T]he Director must have some discretion to balance these countervailing considerations in a delivery call." *Id.* "'If this Court were to rule the Director lacks the power in a delivery call to evaluate whether the senior is putting the water to beneficial use, we would be ignoring the constitutional requirement that priority over water be extended only to those using the water.'" *In re Distribution of Water to Various Water Rights Held by or for the Ben. of A&B Irr. Dist.*, 155 Idaho at 652, 315 P.3d at 840 (quoting *American Falls*, 143 Idaho at 876, 154 P.3d at 447).

10. In responding to a delivery call under the CM Rules, the Director "may employ a baseline methodology as a starting point for considering material injury," provided the baseline methodology otherwise comports with the prior appropriation doctrine as established by Idaho law. *In re Distribution of Water to Various Water Rights Held by or for the Ben. of A&B Irr. Dist.*, 155 Idaho at 653, 315 P.3d at 841; *see Methodology Remand Order* at 17.

11. Once the Director determines "that material injury is occurring or will occur," junior appropriators subject to the delivery call bear "the burden of proving that the call would be futile or to challenge, in some other constitutionally permissible way, the senior's call." *American Falls*, 143 Idaho at 878, 154 P.3d at 449; *Methodology Remand Order* at 31. Junior appropriators have the burden of proving by clear and convincing evidence that the delivery call

is futile or otherwise unfounded. *In re Distribution of Water to Various Water Rights Held by or for the Ben. of A&B Irr. Dist.*, 155 Idaho at 653, 315 P.3d at 841.

12. "This case illustrates the tension between the first in time and beneficial use aspects of the prior appropriation doctrine." *In re Distribution of Water to Various Water Rights Held by or for the Ben. of A&B Irr. Dist.*, 155 Idaho at 650, 315 P.3d at 838. The Idaho Supreme Court has in this case "recognized the critical role of the Director in managing the water resources to accommodate both first in time and beneficial use aspects: 'Somewhere between the absolute right to use a decreed water right and an obligation not to waste it and to protect the public's interest in this valuable commodity, lies an area for the exercise of discretion by the Director.'" *Id.* at 651, 315 P.3d at 839 (quoting *American Falls*, 143 Idaho at 880, 154 P.3d at 451). Thus, in this case the Director may use "a baseline methodology, both as a starting point for consideration of the Coalition's call and in determining the issue of material injury." *Id.* at 650-51, 315 P.3d at 838-39. However, "[i]f changing conditions establish that material injury is greater than originally determined pursuant to the baseline analysis, then adjustments to the mitigation obligation of the juniors must be made when the Director undertakes his mid-season calculations." *Methodology Remand Order* at 18.

13. In the context of conjunctive administration, the Director's methodology for projecting material injury does not impose an obligation upon members of the SWC to reprove their water rights. To the extent water is available, members of the SWC are authorized to divert and store water in accordance with the terms of their licenses or decrees. Nothing established herein reduces that authorization. The question that the CM Rules require the Director to answer in this proceeding is, when water is not available to fill the water rights of the SWC, how much water is reasonably necessary for the SWC to accomplish the beneficial purpose of raising crops; because what is needed to irrigate crops may be less than the decreed or licensed quantities. *American Falls*, 143 Idaho at 880, 154 P.3d at 451; *see In re Distribution of Water to Various Water Rights Held by or for the Ben. of A&B Irr. Dist.*, 155 Idaho at 650, 315 P.3d at 838 ("'[i]t is the settled law of this state that no person can, by virtue of a prior appropriation, claim or hold more water than is necessary for the purpose of the appropriation") (quoting *Washington State Sugar*, 27 Idaho at 44, 147 P. at 1079). Again, "t]he concept that beneficial use acts as a measure and limit upon the extent of a water right is a consistent theme in Idaho water law." *Id.*

14. Holders of senior-priority water rights may receive less than their licensed or decreed quantities and not suffer material injury within the meaning of the CM Rules. As a result, in-season demand should be viewed in light of reasonableness and optimum development of water resources in the public interest. CM Rules 20 and 42; *American Falls*, 143 Idaho at 876-80, 154 P.3d at 447-51; *In re Distribution of Water to Various Water Rights Held by or for the Ben. of A&B Irr. Dist.*, 155 Idaho at 650-652, 315 P.3d at 838-40.

15. Here, the Director has established a methodology for determining material injury to members of the SWC. The methodology predicts material injury to RISD by taking the difference between RISD and the FS. The years 2000 through 2014 were analyzed to select the initial BLY because the period of years captured current irrigation practices in a dry climate. Based upon evaluation of the record, members of the SWC were exercising more reasonable efficiencies during this time period than during the 1990s when supplies were more plentiful. During periods of drought when junior ground water users are subject to curtailment, members

of the SWC should exercise reasonable efficiencies to promote the optimum utilization of the State's water resources. CM Rules 20 and 42; *American Falls,* 143 Idaho at 876-80, 154 P.3d at 447-51; *Clear Springs*, 150 Idaho at 807-10; 252 P.3d at 88-91; *In re Distribution of Water to Various Water Rights Held by or for the Ben. of A&B Irr. Dist.*, 155 Idaho at 650-652, 315 P.3d at 838-40.

16. At this time, with the recognition that the methodology is subject to adjustment and refinement, RISD will be equal to the historic demands associated with the BLY (2006/2008/2012), and will be corrected during the season to account for variations in climate and water supply between the BLY and actual conditions.

17. Recognizing that climate and surface water supplies (natural flow and storage) are inherently variable, the Director's predictions of material injury to RISD and reasonable carryover are based upon the best available information and the best available science, in conjunction with the Director's professional judgment as the manager of the State's water resources. Recognizing his ongoing duty to administer the State's water resources, the Director should use available data, and consider new analytical methods or modeling concepts, to evaluate the methodology. As more data is gathered and analyzed, the Director will review and refine the process of predicting and evaluating material injury. The methodology will be adjusted, if the data supports a change.

18. If the Director predicts that the SWC will be materially injured because of a demand shortfall prediction, either in the preseason or in the midseason, the demand shortfall represents a mitigation obligation that must be borne by junior ground water users. If mitigation water in the amount of the projected RISD shortfall cannot be secured or optioned by junior ground water users to the satisfaction of the Director (*see Order on Petition for Judicial Review* (Jul. 24, 2009) at 19), the Director will curtail junior ground water users to make up any deficit.

19. By requiring that junior ground water users secure mitigation water or have options to acquire water in place during the season of need, the Director ensures that the SWC does not carry the risk of shortage to their supply. By not requiring junior ground water users to deliver or assign mitigation water until the Time of Need, the Director ensures that junior ground water users supply only the amount of mitigation water necessary to satisfy the RISD. All approved methods of mitigation shall be considered in the Director's review of projected RISD shortfall.

20. Unless there is reasonable certainty that junior ground water users can secure the predicted volume of water and provide that water at the Time of Need, the protection afforded to the senior water right holders is compromised. The risk of shortage is then impermissibly shouldered by the SWC. Members of the SWC should have certainty entering the irrigation season and at midseason that mitigation water will be delivered or assigned at the Time of Need, or curtailment of junior ground water rights will be ordered.

21. Because climate and the supply that the SWC appropriated (natural flow and storage) are inherently variable, the Director cannot and should not insulate the SWC against all shortages. The Director can, however, protect the SWC against reasonably predicted shortages to RISD.

22. Currently, the USBR and USACE's Joint Forecast is an indispensible predictive tool at the Director's disposal for predicting material injury to RISD. Given current forecasting techniques, the earliest the Director can predict material injury to RISD with reasonable certainty is soon after the Joint Forecast is issued in early April. The pre-irrigation season supply forecast for A&B and Milner can be predicted solely from the Joint Forecast. To improve the accuracy of prediction, the pre-irrigation season supply forecast for AFRD2, BID, Minidoka, NSCC, and TFCC will currently be predicted from both the Joint Forecast and from flow data at Box Canyon.[9]

23. By shifting the April Forecast Supply prediction curve down one standard error of estimate, the Director purposely underestimates the water supply that is predicted. The Director further guards against RISD shortage by using the 06/08/12 BLY, which has above average diversions, above average ET, below average in-season precipitation, and above average growing degree days. The 06/08/12 average represents years in which water supply did not limit diversions. The Director's prediction of material injury to RISD is purposely conservative. While it may ultimately be determined after final accounting that less mitigation water was owed than was provided, this is an appropriate burden for junior appropriators to carry. Idaho Cost. Art. XV, § 3; Idaho Code § 42-106. Shifting the prediction curve down one standard error of estimate and adoption of a BLY that uses above average diversions, above average temperatures and ET and below average precipitation is necessary to protect senior rights if the Director administers to an amount less than the full decreed quantity of the SWC's rights. *Methodology Remand Order* at 33, 35.

24. The Director will review, at the end of the season, the volume and efficiencies of application of surface water, the amount of mitigation water provided by junior ground water users, and may, in the exercise of his professional judgment, readjust the reasonable carryover shortfalls to reflect these considerations.

25. "Storage water is water held in a reservoir and is intended to assist the holder of the water right in meeting their decreed needs." *American Falls*, 143 Idaho at 878, 154 P.3d at 449. "Carryover is the unused water in a reservoir at the end of the irrigation year which is retained or stored for future use in years of drought or low-water." *Id.* Under Idaho Code, "[o]ne may acquire storage water rights and receive a vested priority date and quantity, just as with any other water right," but "[t]here is no statutory provision for obtaining a decreed right to 'carryover' water." *Id.* Rather, carryover is a "component of the storage right." *Order on Petition for Judicial Review* (Jul. 24, 2009) at 20. Storage carryover is "permissible . . . absent abuse." *American Falls*, 143 Idaho at 880, 154 P.3d at 451.

26. The storage reservoirs implicated in this proceeding were intended to provide supplemental supplies of water "to create a buffer against the uncertainty of the weather." *Opinion Constituting Findings of Fact, Conclusions of Law and Recommendation* (April 29, 2008) at 6. "The history of the development of the reservoir system, most recently Palisades, makes it clear that storage of water was a primary purpose to prevent disaster during periods of shortage as have been experienced in the recent past." *Id.* at 60. The purpose of carryover also

[9] The method for predicting the natural flow supply may be subject change based upon improved predictive models.

is "insurance against the risk of future shortage." *Order on Petition for Judicial Review* (Jul. 24, 2009) at 20.

27. CM Rule 42.01 sets forth factors the Director "may consider in determining whether the holders of water rights are suffering material injury and using water efficiently and without waste." CM Rule 42.01 does not limit the Director's determination of reasonable carryover to consideration of the factors enumerated in CM Rule 42.01g, but only requires that the Director consider those enumerated factors. One such factor is "[t]he extent to which the requirements of the holder of a senior priority water right could be met with the user's existing facilities and water supplies." CM Rule 42.01g. This factor is qualified, however, by the provision that "the holder of a surface water storage right shall be entitled to maintain a reasonable amount of carry-over storage to assure water supplies for future dry years." CM Rule 42.01g. Thus, CM Rule 42.01g does not require water right holders to exhaust their storage water supplies prior to making a delivery call under the CM Rules. This is consistent with the purposes of the storage reservoirs and the carryover components of the storage water rights.

28. In considering CM Rule 42.01g in *American Falls*, the Idaho Supreme Court framed the SWC's challenge to the "reasonable carryover" provision as presenting the question of whether the holders of storage water rights are "entitled to insist on all available water to carryover for future years in order to assure that their full storage water is met (regardless of need)," *American Falls,* 143 Idaho at 879, 154 P.3d at 450, and answered this question in the negative:

> At oral argument, one of the irrigation district attorneys candidly admitted that their position was that they should be permitted to fill their entire storage water right, regardless of whether there was any indication that it was necessary to fulfill current or future needs and even though the irrigation districts routinely sell or lease the water for uses unrelated to the original rights. This is simply not the law of Idaho. While the prior appropriation doctrine certainly gives pre-eminent rights to those who put water to beneficial use first in time, this is not an absolute rule without exception. As previously discussed, the Idaho Constitution and statutes do not permit waste and require water to be put to beneficial use or be lost. Supra, paragraph 11.

Id. at 880, 154 P.3d at 451.

29. As discussed in the Findings of Fact, reasonable carryover is determined by projecting the water supply for the system. This is accomplished by projecting the 2002/2004 supply and the 2006/2008/2012 demand. Next, the Director examines the average annual rate of fill of each SWC entity's reservoir space to determine each entity's relative probability of fill. Finally, the Director examines the average annual carryover for prior comparable water conditions by reviewing Heise natural flow.

30. On or before November 30, the Department will issue estimates of actual carryover and reasonable carryover shortfall volumes for all members of the SWC. These estimates will establish the obligation of junior ground water users in providing water to the SWC for reasonable carryover shortfall. Fourteen (14) days following the issuance by the

Department of reasonable carryover short fall obligations, junior ground water users will be required to establish, to the satisfaction of the Director, their ability to supply a volume of storage water or to conduct other approved mitigation activities that will provide water to the injured members of the SWC equal to the reasonable carryover shortfall for all injured members of the SWC. If junior ground water users cannot provide this information, the Director will issue an order curtailing junior ground water rights.

31. Recognizing that reservoir space held by members of the SWC may fill, and to prevent the waste of water, junior ground water users are not required to deliver or assign the volume of reasonable carryover until after the Day of Allocation (defined in footnote 11, *infra*). Junior ground water users are obligated to hold the secured or optioned mitigation water until reservoir space held by the SWC fills. If the reservoir space does not fill, junior ground water right holders must deliver or assign the secured or optioned mitigation water to the senior water right holders up to the amount of storage space that did not fill.

32. The Director recognizes that his analysis of the obligation for reasonable carryover differs from his analysis for RISD obligations. In predicting RISD shortages, the Director is able to premise his determination on the Joint Forecast. The Director requires junior ground water users to provide the entire RISD shortage because the Joint Forecast allows determination of material injury with reasonable certainty.

33. In the fall of the subsequent irrigation season, the Director cannot, with reasonable certainty, predict material injury to reasonable carryover. As found by the Hearing Officer, "Anticipating the next season of need is closer to faith than science." R. Vol. 37 at 7109.

ORDER

Consistent with the forgoing, the Director HEREBY ORDERS that, for purposes of determining material injury to RISD and reasonable carryover, the following steps will be taken:

1. Step 1: By April 1, members of the SWC will submit electronic shape files to the Department delineating the total anticipated irrigated acres for the upcoming year within their water delivery boundary or confirm in writing that the existing electronic shape file submitted by SWC has not varied by more than five percent. Department staff will review submitted shapefiles and modify them as necessary to ensure that: (1) the total acreage count does not exceed the decreed number of acres; (2) all of the irrigated land is located within the decreed place of use; and (3) acres are not counted more than once due to overlapping polygons within a shape file or between shape files submitted by different SWC members. Because the SWC members can best determine the irrigated acres within their service area, the SWC should be responsible for submitting the information to the Department. If this information is not timely submitted, the Department will determine the total irrigated acres based upon past cropping patterns and current satellite and/or aerial imagery. If a SWC member fails or refuses to identify the number of irrigated acres within its service area by April 1, the Department will be cautious about recognizing acres as being irrigated if there is uncertainty about whether the acres are or will be irrigated during the upcoming irrigation season. The Department will electronically post electronic shape files for each member of the SWC for the current water year for review by the

parties. In determining the total irrigated acreage, the Department may account for supplemental ground water use. The Department currently does not have sufficient information to accurately determine the contribution of supplemental ground water to lands irrigated with surface water by the SWC. If and when reliable data is available to the Department, the methodology will be amended to account for the supplemental ground water use.

2. If the acreage count is under reported by more than five percent of the irrigated acreage limit of the water right, then the Department will assess the impact of this reduction in use of the water right on any mitigation requirement.

3. Step 2: Typically within the first two weeks of April, the USBR and USACE issue their Joint Forecast that predicts an unregulated inflow volume at the Heise Gage for the period April 1 through July 31. Within fourteen (14) days after issuance of the Joint Forecast, the Director will issue a final order predicting the April FS for the water year for each SWC entity. The Director will compare the April FS for each SWC entity to the BD for each SWC entity to determine if a demand shortfall ("DS") is anticipated for the upcoming irrigation season. The April FS for each SWC entity is the sum of the forecasted natural flow supply and the forecasted storage allocation for each SWC entity. The forecasted natural flow supply will be computed with regression algorithms. The forecasted storage allocation will be determined by comparing storage accruals in an analogous year(s). The ESPA Model will be run to determine the curtailment date which will produce a volume of water equal to the DS in the near Blackfoot to Minidoka reach. The model simulation will be run at steady state within the area of common ground water supply as described by CM Rule 50.01.

4. Step 3: By May 1, or within fourteen (14) days from issuance of the final order predicting the April FS, whichever is later in time, junior ground water users with approved mitigation plans for delivery of water must secure, to the satisfaction of the Director, a volume of water equal to their proportionate share of the April DS unless the April DS is revised as explained below in paragraph 6. If junior ground water users secured water for a reasonable carryover shortfall to an individual SWC member in the previous year, the current-year mitigation obligation to the individual SWC member will be reduced by the quantity of water secured for the reasonable carryover shortfall. The secured water will not be required to be delivered to the injured members of the SWC until the Time of Need.

5. Step 4: As soon as practical after the deadline for junior ground water users with approved mitigation plans to provide notice of secured water, the Director will issue an order curtailing junior ground water users who: (1) do not have approved mitigation plans; (2) fail to secure the required water consistent with their approved mitigation plans; or (3) otherwise fail to comply with their approved mitigation plans.[10]

6. If, at any time prior to the Director's final determination of the April FS, the Director can determine with certainty that any member of the SWC has diverted more natural

[10] This presumes that any reasonable carryover obligation has been met, and that junior ground water users are not already under prior curtailment from deficiencies in meeting the previous year's obligation.

flow than predicted, or has accrued more storage than predicted, the Director will revise his initial, projected demand shortfall determination.

7. Step 5: If the storage allocations held by members of the SWC fill, there is no reasonable carryover shortfall. If the storage allocations held by members of the SWC do not fill, within fourteen (14) days following the publication of Water District 01's initial storage report, which typically occurs soon after the Day of Allocation,[11] the volume of water secured by junior ground water users to fulfill the reasonable carryover shortfall shall be made available to injured members of the SWC. The amount of reasonable carryover to be provided shall not exceed the empty storage space on the Day of Allocation for that entity. If water is owed in addition to the reasonable carryover shortfall volume, this water shall be delivered or assigned to members of the SWC at the Time of Need, described below. The Time of Need will be no earlier than the Day of Allocation.

8. Step 6: Approximately halfway through the irrigation season, but following the events described in Step 5, the Director will, for each member of the SWC: (1) recalculate RISD; (2) issue a revised FS and (3) estimate the Time of Need date.[12]

9. RISD will be calculated utilizing the project efficiency, BD, and the cumulative actual CWN determined up to that point in the irrigation season. The cumulative CWN volume will be calculated for all land irrigated with surface water within the boundaries of each member of the SWC. Volumetric values of CWN will be calculated using ET and precipitation values from the USBR's AgriMet program, irrigated areas provided by each entity, and crop distributions based on NASS data

10. The FS for each SWC is the sum of the year-to-date actual natural flow diversions, the forecasted natural flow supply for the remainder of the season, and the storage allocation for each member of the SWC. The forecasted natural flow supply for the remainder of the season will be based on regression analysis. The storage allocation will be based on the actual preliminary storage allocations issued by the BOR and Water District 01. If the BOR and Water District 01 have not yet allocated stored water to spaceholders, the Department will predict the storage allocations based on an analogous year(s).

11. The calendar day determined to be the Time of Need is established by predicting the day in which the remaining storage allocation will be equal to reasonable carryover, or the difference between the 06/08/12 average demand and the 02/04 supply. The Time of Need will not be earlier than the Day of Allocation.

12. This information will be used to recalculate RISD and adjust the projected DS for each member of the SWC. The Director will then issue revised RISD and DS values. Any

[11] The Day of Allocation is the time in the irrigation season when the Water District 01 watermaster is able to issue allocations to storage space holders after the reservoir system has achieved its maximum physical fill, maximum water right accrual, and any excess spill past Milner Dam has ceased. Tr. p. 902, lns. 7-25; p. 903, lns. 1-10.

[12] At the earliest established Time of Need for any member of the SWC, junior ground water users are required to provide remaining mitigation to all materially injured members of the SWC.

increase to the projected DS for each SWC entity is an additional mitigation obligation of the junior ground water users.

13. Upon a determination of an additional mitigation obligation, junior ground water users will be required to establish, to the satisfaction of the Director, their ability to secure a volume of storage water pursuant to an approved mitigation plan or to conduct other approved mitigation activities that will deliver the additional mitigation obligation water to the injured members of the SWC at the Time of Need. If junior ground water users fail or refuse to submit this information within fourteen (14) days from issuance of a Step 6 order, the Director will issue an order curtailing junior ground water users.[13] The ESPA Model will be run to determine the priority date to produce the necessary additional mitigation obligation volume within the area of common ground water supply, as described by CM Rule 50.01.

14. Step 7: Shortly before the estimated Time of Need, but following the events described in Steps 5 and 6, the Director will, for each member of the SWC: (1) recalculate RISD; (2) issue a revised FS; and (3) establish the Time of Need. The revised FS for each SWC entity is the sum of the year-to-date actual natural flow diversions, the forecasted natural flow supply for the remainder of the season, and the storage allocation for each member of the SWC. The forecasted natural flow supply for the remainder of the season will be based on analogous year(s) with similar Blackfoot to Milner reach gains. The storage allocation will be based on the actual preliminary storage allocations issued by the BOR and Water District 01.

15. This information will be used to recalculate RISD and adjust the projected DS for each member of the SWC. RISD will be calculated utilizing the project efficiency, BD, and the cumulative actual CWN determined up to that point in the irrigation season. The Director will then issue revised RISD and DS values.

16. Step 8: At the Time of Need, junior ground water users are required to deliver to each injured member of the SWC the Step 7 revised DS calculated at the Time of Need. Alternatively, any additional mitigation obligation calculated in Step 6 and Step 7 can be satisfied from the each SWC member's reasonable carryover if (a) the reasonable carryover exceeds the additional mitigation obligation, and (b) the junior ground water users secure sufficient water to replace the reasonable carryover pursuant to an approved mitigation plan.

17. The Director will review, at the end of the season, the volume and efficiencies of application of surface water, the amount of mitigation water delivered by junior ground water users, and may, in the exercise of his professional judgment, readjust the reasonable carryover shortfalls to reflect these considerations.

18. Step 9: Following the end of the irrigation season (on or before November 30), the Department will determine the total actual volumetric demand and total actual CWN for the entire irrigation season. This information will be used for the analysis of reasonable carryover

[13] This presumes that any reasonable carryover obligation has been met, and that junior ground water users are not already under prior curtailment from deficiencies in meeting the previous year's obligation.

shortfall, selection of future BLY, and for the refinement and continuing improvement of the method for future use.

19. On or before November 30, the Department will issue estimates of actual carryover and reasonable carryover shortfall volumes for all members of SWC. These estimates will be based on, but not limited to, the consideration of the best available water diversion and storage data from Water District 01, return flow monitoring, comparative years, and RISD. These estimates will establish the obligation of junior ground water users in providing water to the SWC for reasonable carryover shortfall. Fourteen (14) days following the issuance by the Department of reasonable carryover short fall obligations, junior ground water users will be required to establish, to the satisfaction of the Director, their ability to supply a volume of storage water or to conduct other approved mitigation activities that will provide water to the injured members of the SWC equal to the reasonable carryover shortfall for all injured members of the SWC. If junior ground water users cannot provide this information, the Director will issue an order curtailing junior ground water rights.

IT IS FURTHER ORDERED that this Fourth Methodology Order supersedes all previously issued methodology orders in this matter.

Dated this 19th day of April 2016.

GARY SPACKMAN
Director

Deborah J. Gibson

Deborah Gibson
Administrative Assistant to the Director

EXPLANATORY INFORMATION TO ACCOMPANY A FINAL ORDER

(To be used in connection with actions when a hearing was not held)

(Required by Rule of Procedure 740.02)

The accompanying order is a "**Final Order**" issued by the department pursuant to section 67-5246, Idaho Code.

PETITION FOR RECONSIDERATION

Any party may file a petition for reconsideration of a final order within fourteen (14) days of the service date of this order as shown on the certificate of service. **Note: The petition must be received by the Department within this fourteen (14) day period.** The department will act on a petition for reconsideration within twenty-one (21) days of its receipt, or the petition will be considered denied by operation of law. See section 67-5246(4), Idaho Code.

REQUEST FOR HEARING

Unless the right to a hearing before the director or the water resource board is otherwise provided by statute, any person who is aggrieved by the action of the director, and who has not previously been afforded an opportunity for a hearing on the matter shall be entitled to a hearing before the director to contest the action. The person shall file with the director, within fifteen (15) days after receipt of written notice of the action issued by the director, or receipt of actual notice, a written petition stating the grounds for contesting the action by the director and requesting a hearing. See section 42-1701A(3), Idaho Code. **Note: The request must be received by the Department within this fifteen (15) day period.**

APPEAL OF FINAL ORDER TO DISTRICT COURT

Pursuant to sections 67-5270 and 67-5272, Idaho Code, any party aggrieved by a final order or orders previously issued in a matter before the department may appeal the final order and all previously issued orders in the matter to district court by filing a petition in the district court of the county in which:

i. A hearing was held,
ii. The final agency action was taken,
iii. The party seeking review of the order resides, or
iv. The real property or personal property that was the subject of the agency action is located.

The appeal must be filed within twenty-eight (28) days of: a) the service date of the final order, b) the service date of an order denying petition for reconsideration, or c) the failure within twenty-one (21) days to grant or deny a petition for reconsideration, whichever is later. See section 67-5273, Idaho Code. The filing of an appeal to district court does not in itself stay the effectiveness or enforcement of the order under appeal.

Revised July 1, 2010

EXHIBIT 317

Surface Water Coalition Delivery Call, Amended 5th Methodology and April 2023 As-Applied Orders

FAQs

- Why did IDWR change the Methodology?

  IDWR is obligated to update the Methodology to incorporate new climate and hydrologic data and to ensure adequate protection for senior water users from injury. The new Methodology revises important elements used to determine in-season injury to water supplies and end-of-season injury to storage reservoir carryover. It also revises the method used to calculate curtailment dates, relying on what is referred to as "transient" model analysis, in a manner that may result in earlier curtailment dates than previously predicted.

- What changes did IDWR make to the Methodology?

  IDWR made the following changes to its Methodology: (1) updated climate, hydrologic, and demand data used by the Methodology to determine injury, (2) updated "base line year," (3) updated "reasonable carryover" volumes for the Surface Water Coalition (SWC), and (4) changed how the Eastern Snake Plain Aquifer Model (ESPAM 2.2) is deployed to calculate a priority curtailment date from "steady state" to transient analysis.

- Why did IDWR change the methodology to a transient model?

  The Director has concluded that using the ESPA model in steady-state mode is no longer legally supportable because steady state does not provide water at the time, place, and quantity needed by the senior water user.

- Does this mean that 940,000 acres will be curtailed along the East Snake Plain Aquifer?

  No, many irrigated acres are covered by approved mitigation plans and are not subject to curtailment.

- How many acres will be curtailed that IDWR estimates are NOT part of an approved mitigation plan?

  IDWR will not have an estimate for this number until it works through curtailment with individual water right holders.

- How can there be curtailment in a year when we have so much snow in the hills?

  The As-Applied order is an early season prediction of what the water supply for the SWC will be for the upcoming year. The courts have been clear that the Director's predictions must favor the senior water users. And while there is a good snowpack in the hills above the ESPA, that is only part of the water supply for the SWC. Additional supply comes from recharge from the aquifer and that is at a record low. Plus, we are coming out of two years of drought and the existing storage supply was low.

- Are water users immediately subject to curtailment with the issuance of the Methodology and As-Applied orders?

No. The Director has scheduled a contested case hearing (June 6 – 10, 2023) to allow parties to submit testimony and evidence regarding the changes to the Methodology implemented by the Director. Because of the pending hearing, the Director will delay issuing a curtailment notice to Snake River junior water users until after the hearing. This means junior ground water pumpers who do not have approved mitigation plans in place will have a reprieve from curtailment until late June. Junior water users should wait for specific notice and direction from IDWR as to how their individual water rights are affected by this decision. However, water right holders who are junior to 1953 should work with IDWR to understand how their water right could be impacted in the case they are not in compliance and a party to an approved mitigation plan.

The following questions all assume that the Director issues a curtailment order and the water rights at issue are junior to the curtailment date in the order:

- What happens if I am participating in an approved mitigation plan?

  If you are participating in an approved mitigation plan and the mitigation plan is being complied with, you will not be subject to curtailment.

- What happens if I am participating in an approved mitigation plan but the plan is not being complied with?

  You will be subject to curtailment.

- What happens if I am NOT part of an approved mitigation plan?

  You will be subject to curtailment. However, you do have the option to join an approved mitigation plan. This is based on the parties in the approved mitigation plan agreeing to add additional members.

- What happens if I am a party to, and meet the criteria of IGWA's 2009 Storage Water Delivery Mitigation Plan?

  If IGWA delivers storage water to the SWC in a volume equal to the injury determination, participating members are not subject to curtailment. However, this mitigation plan does not provide safe harbor for future injury determination and IGWA must always secure storage water commensurate with the injury determination regardless of the size of injury (e.g., in July of 2021, the injury determination was ~170 KAF). For example, at the mid-season adjustment, if IDWR determines the injury is greater than its April determination, IGWA will have to secure additional storage water or be subject to curtailment during the season after crops are planted.

- What if I am a party to, and meet the criteria of the SWC-IGWA 2015 settlement agreement?

  The 2015 settlement agreement was approved as a mitigation plan by IDWR. So long as the ground water districts comply with the mitigation plan, members of the ground water districts are not subject to curtailment.

- What if I am a city participating in a mitigation plan?

  If you are a city participating in an approved mitigation plan and the mitigation plan is being complied with, you are not subject to curtailment.

- What if I am a city NOT participating in a mitigation plan?

  You will be subject to curtailment. However, you do have the option to join an approved mitigation plan. This is based on the parties in the approved mitigation plan to agree to add additional members.

- What if I am a processor participating in an approved mitigation plan?

  If you are a processor participating in an approved mitigation plan and the mitigation plan is being complied with, you are not subject to curtailment.

- What if I am a processor NOT participating in an approved mitigation plan?

  You are subject to curtailment. However, you do have the option to join an approved mitigation plan. This is based on the parties in the approved mitigation plan to agree to add additional members.

- Can I submit a mitigation plan now and get it approved in time for this coming irrigation season?

  It is unlikely that a mitigation plan can be approved before a potential curtailment order is issued. Once a plan is submitted, the plan must be advertised and is then subject to a protest deadline. The plan is subject to hearing if protested or if the Director determines a hearing is necessary. This process can take many months.

EXHIBIT 318

IDAHO DEPARTMENT OF WATER RESOURCES

SWC methodology – calculation of priority dates for curtailment of junior groundwater users

Presented to the SWC Methodology Technical Working Group

Jennifer Sukow, P.E., P.G.

November 28, 2022

Exh. No. 6
Date 5-10-23
Name Jennifer Sukow
M & M Court Reporting

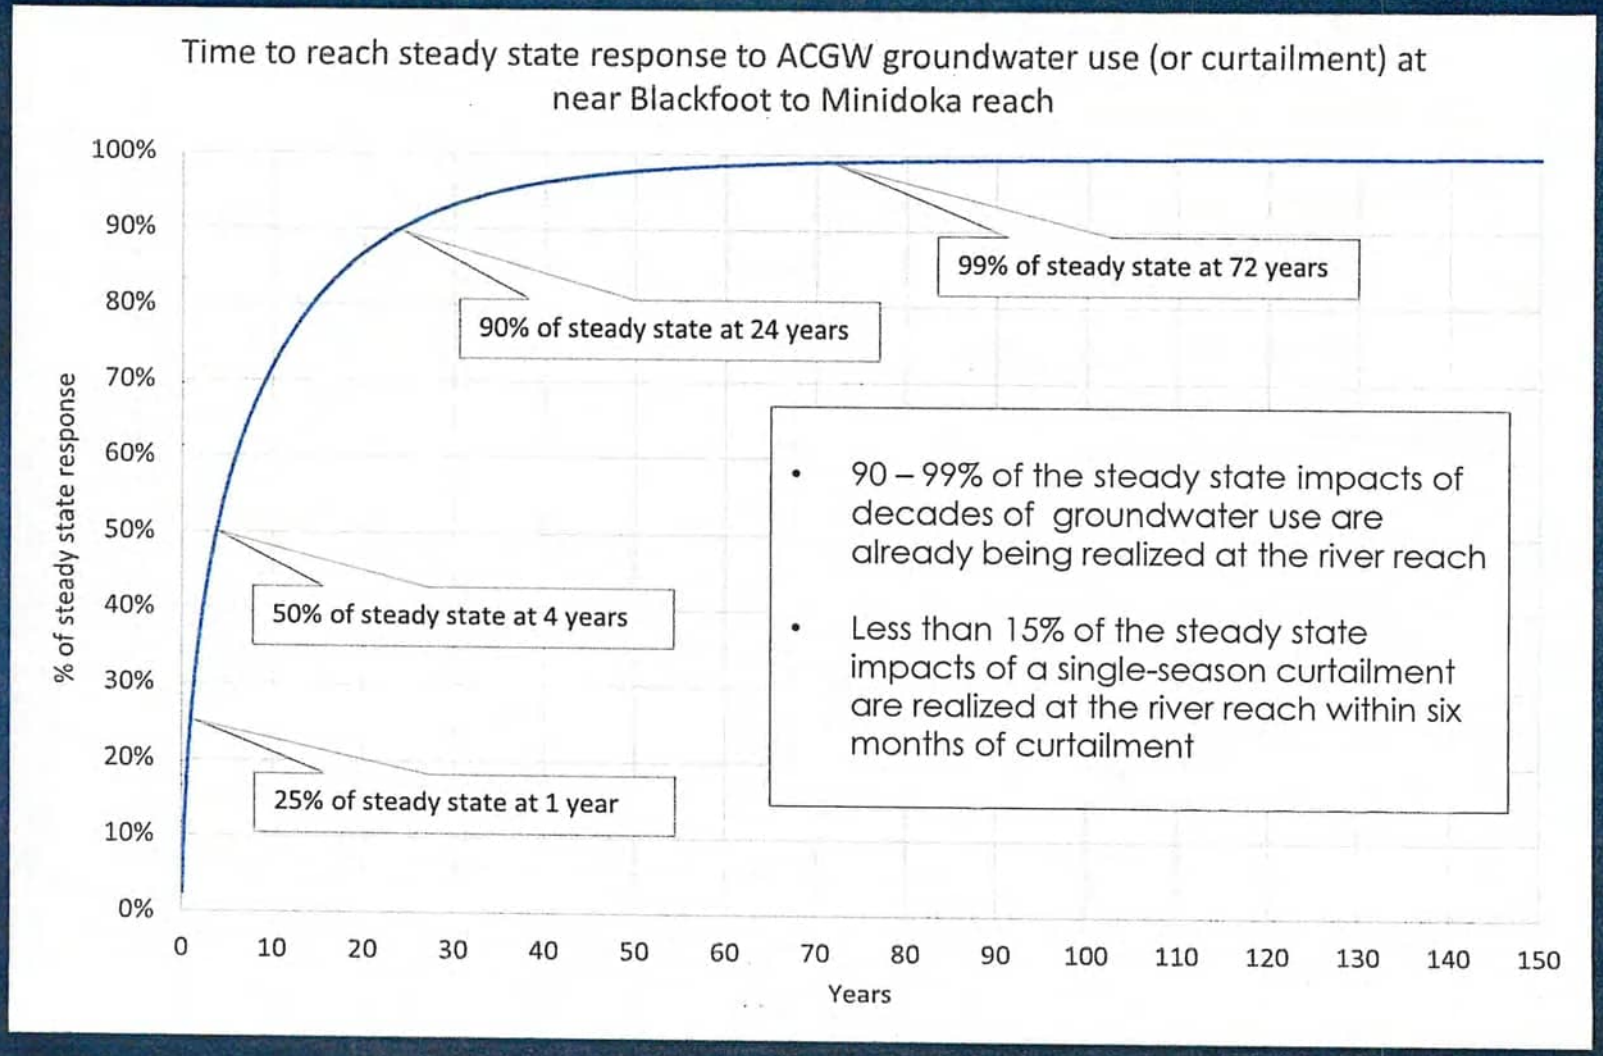
Methodology reference

- Curtailment date calculation (Step 2) (Page 36 of Methodology)
  - The ESPA Model will be run to determine the curtailment date which will produce a volume of water equal to the DS in the near Blackfoot to Minidoka reach. The model simulation will be run at steady state within the area of common ground water supply as described by CM Rule 50.01.
- Curtailment date calculation (Step 6) (Page 38 of Methodology)
  - Upon a determination of an additional mitigation obligation, junior ground water users will be required to establish, to the satisfaction of the Director, their ability to secure a volume of storage water pursuant to an approved mitigation plan or to conduct other approved mitigation activities that will deliver the additional mitigation obligation water to the injured members of the SWC at the Time of Need. If junior ground water users fail or refuse to submit this information within fourteen (14) days from issuance of a Step 6 order, the Director will issue an order curtailing junior ground water users.[13] The ESPA Model will be run to determine the priority date to produce the necessary additional mitigation obligation volume within the area of common ground water supply, as described by CM Rule 50.01.

Methodology reference

- Curtailment for carryover shortfall (Step 9) (Page 39 of Methodology)
  - Fourteen (14) days following the issuance by the Department of reasonable carryover shortfall obligations, junior ground water users will be required to establish, to the satisfaction of the Director, their ability to supply a volume of storage water or to conduct other approved mitigation activities that will provide water to the injured members of the SWC equal to the reasonable carryover shortfall for all injured members of the SWC. If junior ground water users cannot provide this information, the Director will issue an order curtailing junior ground water rights.

Presentation outline

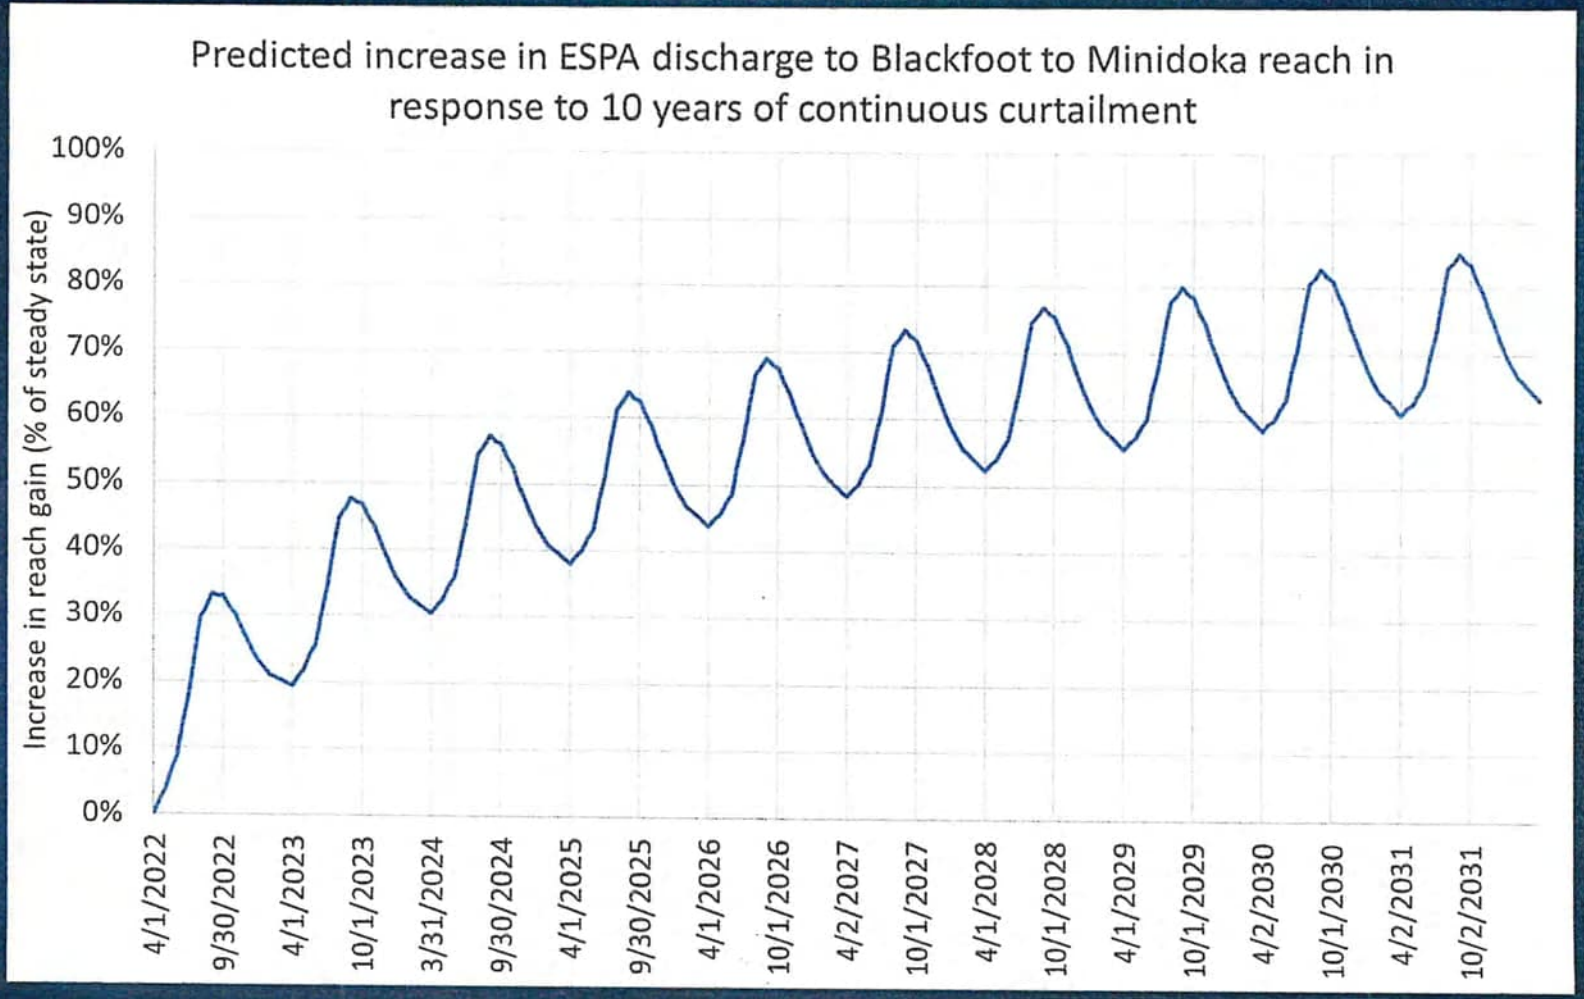


- Steady state vs. transient model simulations
- Transient model results for curtailment priority dates in 2022 orders
- Examples of transient model simulations for calculation of curtailment priority dates
  - Assumptions for transient model simulations
  - Comparison of priority dates and acres curtailed for various shortfall volumes
  - Transient analyses for water years 2021-2022

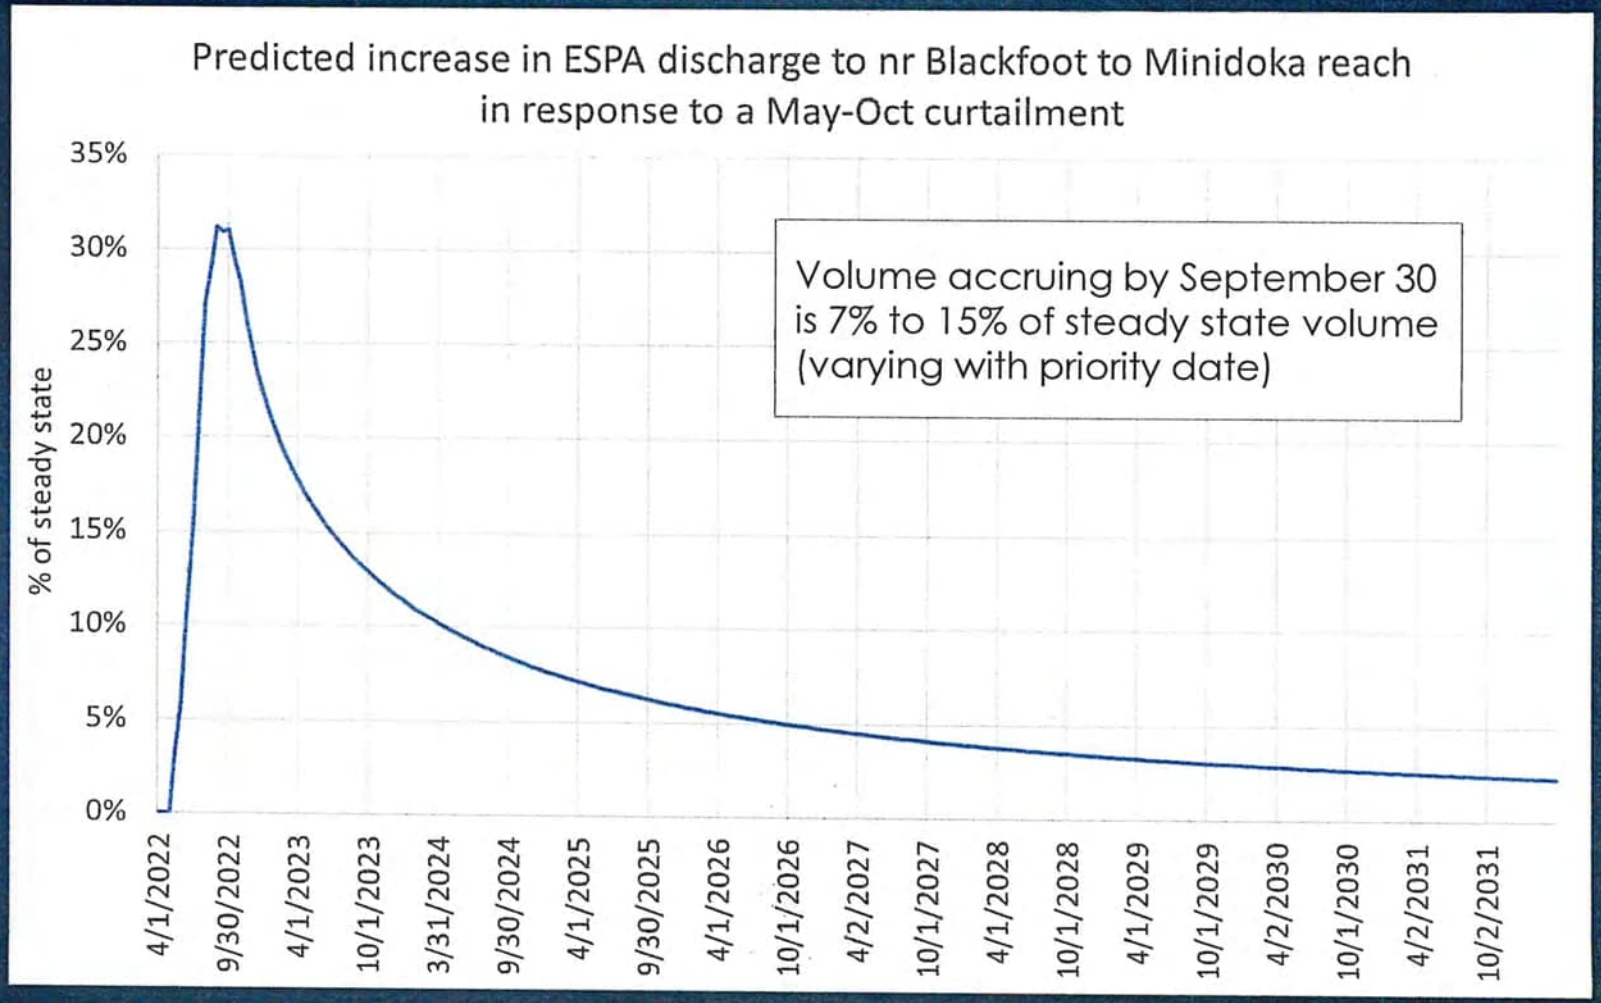
Steady state vs. transient model simulations

- Merriam-Webster definition of *steady state*
  - a state or condition of a system or process that does not change in time

- Steady state ESPAM simulation for calculation of curtailment priority date
  - Predicts long-term response to continuous curtailment of groundwater use at a constant rate for an infinite number of years
  - Result is a prediction of the long-term average annual impact of curtailment on the near Blackfoot to Minidoka reach
  - Curtailments ordered as prescribed in methodology order are not continuous or long-term
  - Groundwater use does not occur at a constant rate throughout the year



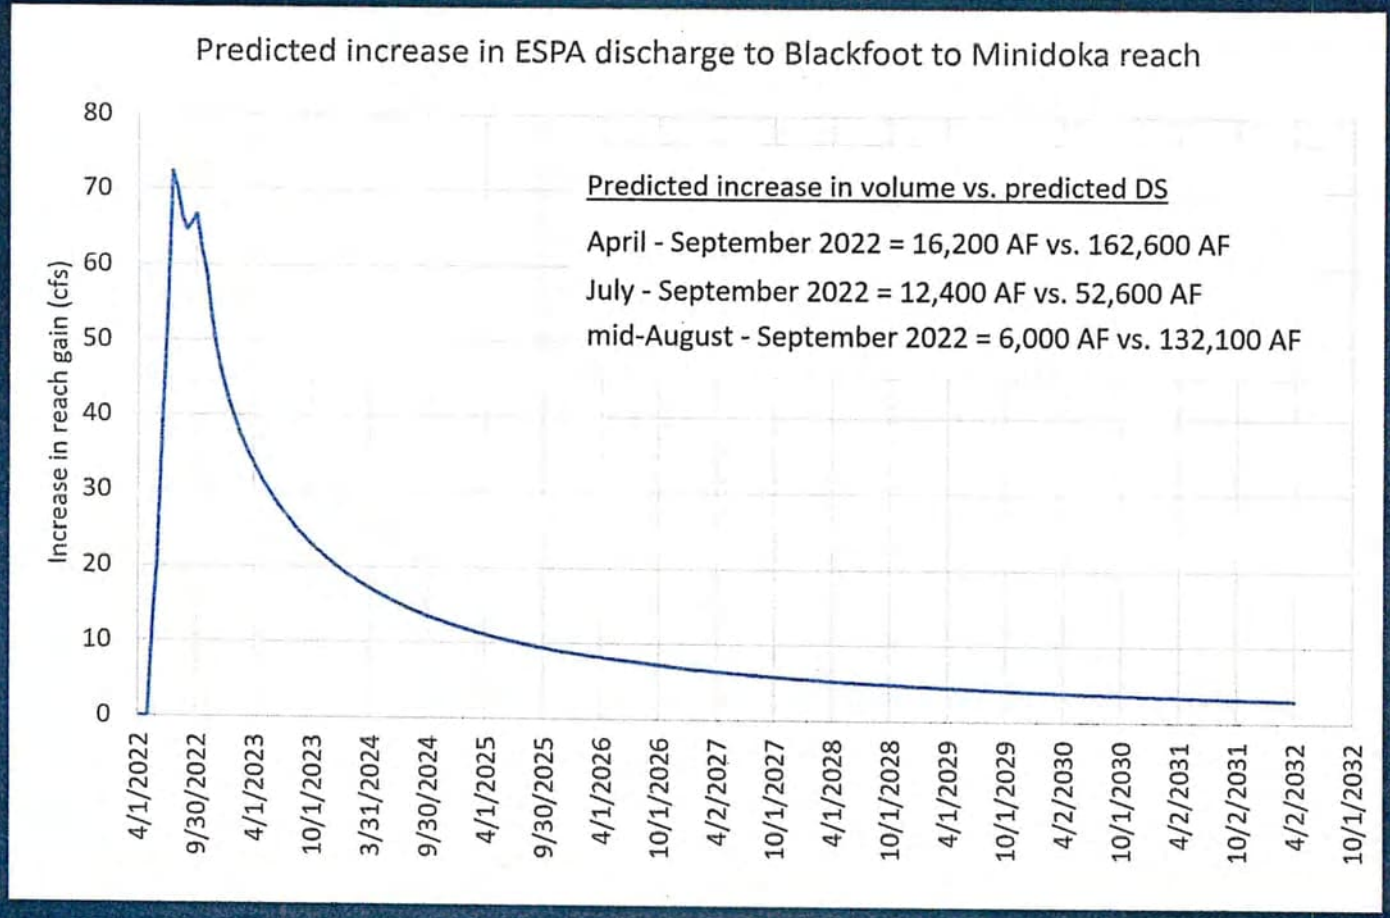
How long does it take to approach steady state conditions?



Steady state vs. transient model simulations

- Merriam-Webster definition of *transient*
  - passing especially quickly into and out of existence
- Transient ESPAM simulation for calculation of curtailment priority date
  - Predicts timing and magnitude of response to time-varying changes in aquifer stress resulting from short-term curtailment of groundwater use to address a predicted shortfall
  - Result is a prediction of the timing and magnitude of the response to time-varying curtailment of groundwater use

Steady state vs. transient model simulations

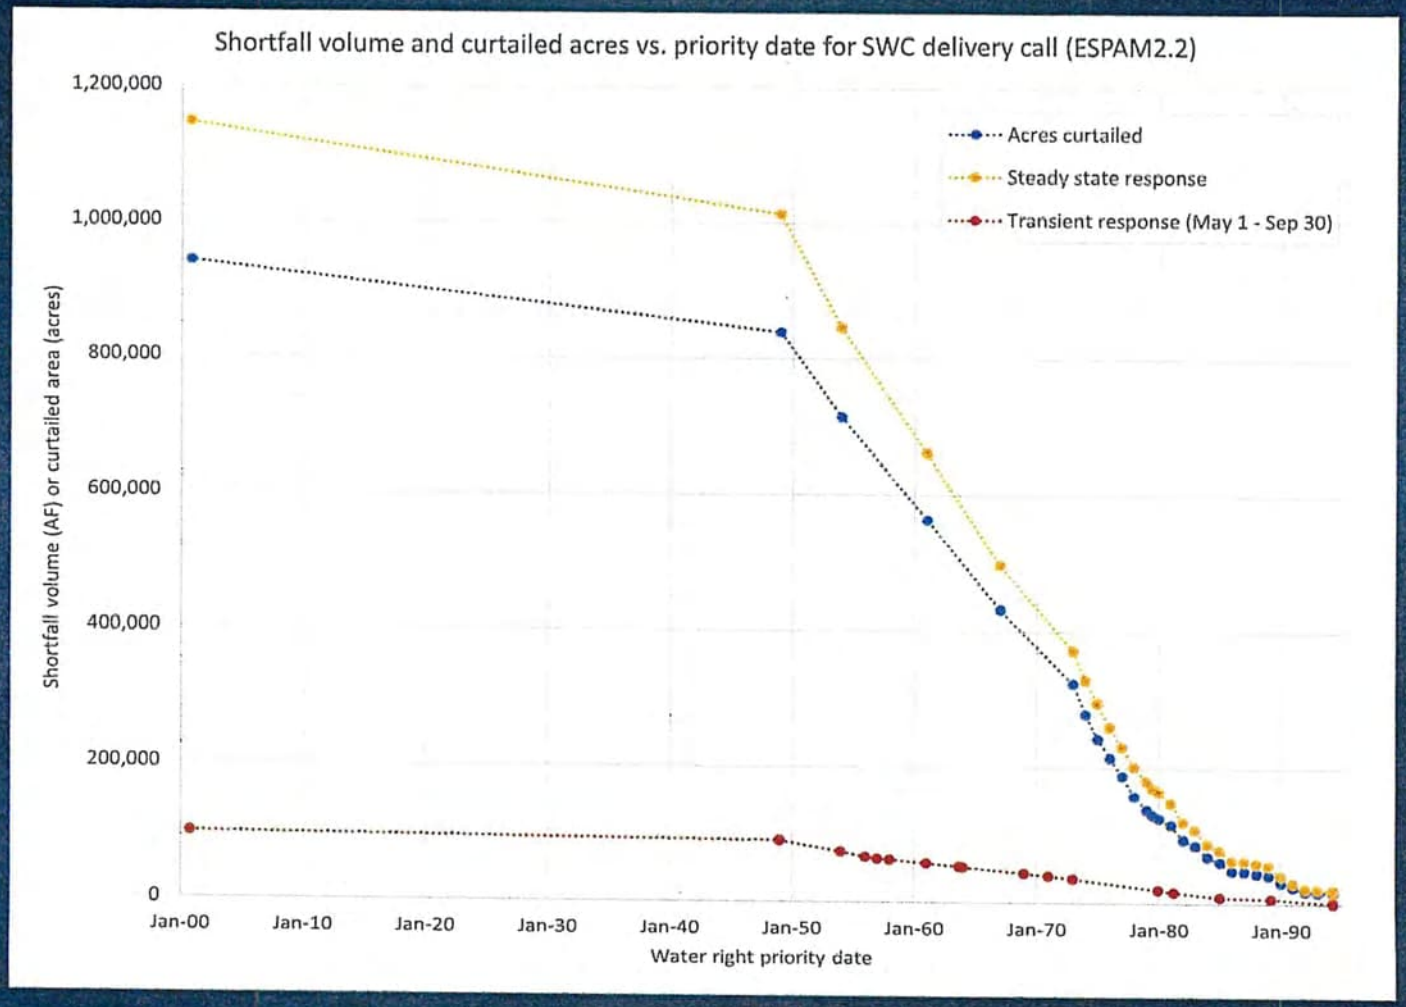


Steady state vs. transient model simulations

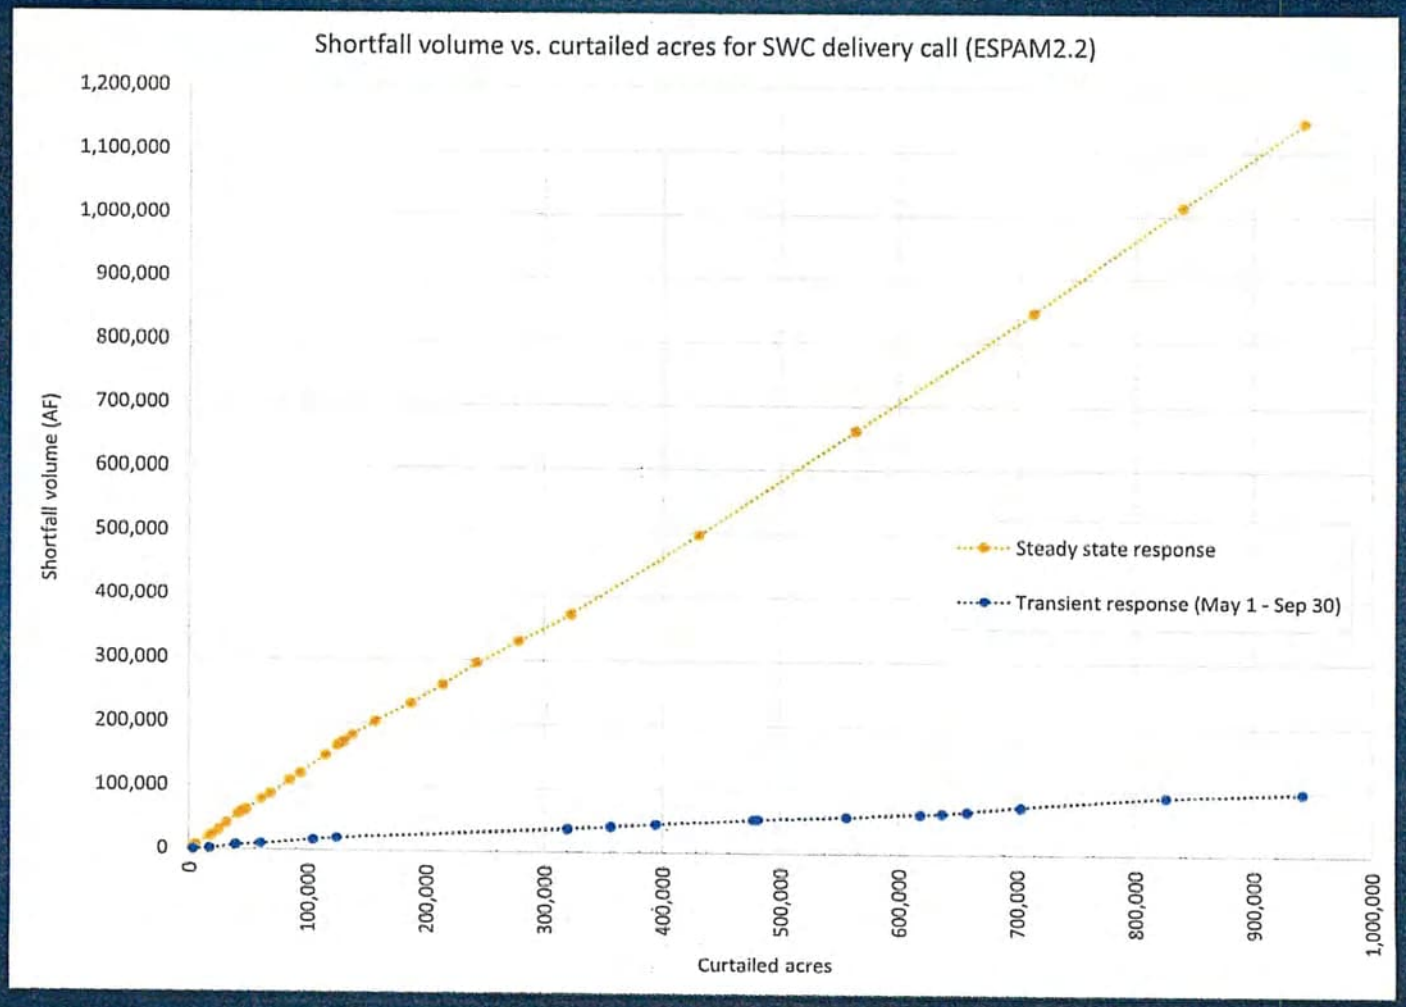
Transient simulation of curtailments ordered in 2022

- 2022 curtailments ordered
  - Curtailment priority dates were calculated based on steady state response at near Blackfoot to Minidoka
  - April 1 DS forecast of 162,600 AF → curtailment junior to December 25, 1979 beginning May
  - July 1 DS Forecast of 52,600 AF → curtailment reduced to junior to March 12, 1989 in July
  - Time of Need Forecast of 132,100 AF → curtailment increased to junior to March 25, 1981 in August
- Transient simulation of these curtailment dates was performed to compare volumes predicted to accrue to near Blackfoot to Minidoka during this season with the predicted DS volumes

Transient simulation of curtailments ordered in 2022

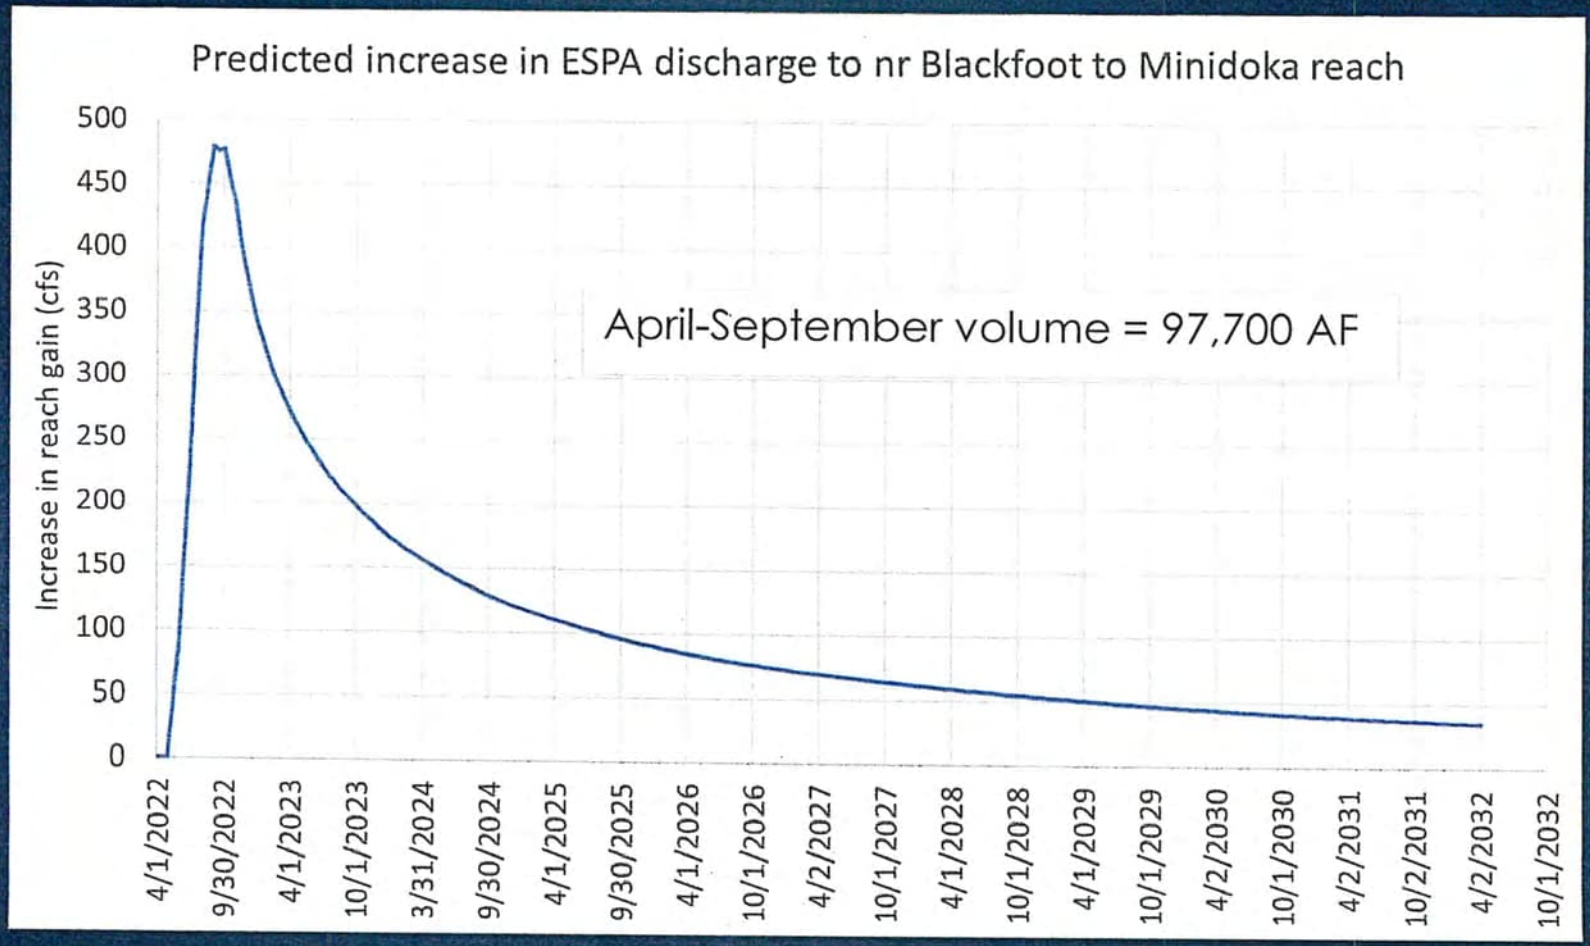


- Volume that would accrue from the ordered curtailments during the period of each shortfall is much less than the predicted shortfall
- Increases in reach gain would continue to accrue in future water years

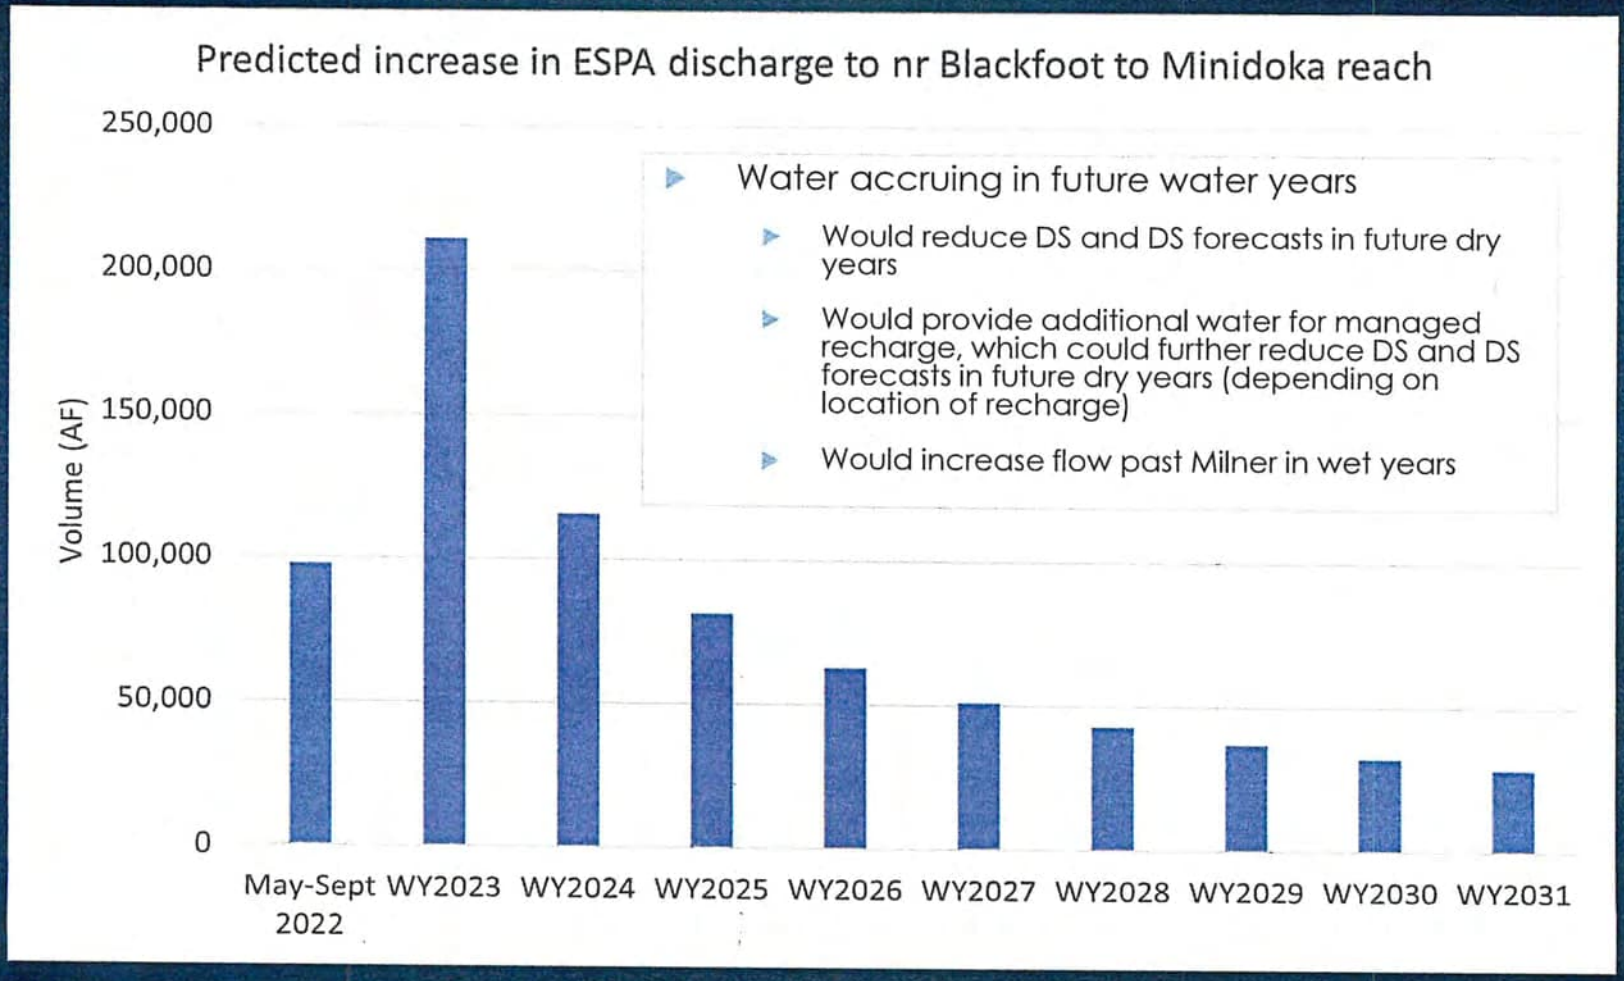


Assumptions for example transient model simulations

- Continue to use methods documented in "Curtailment Scenario" report (Sukow, 2021)
  https://research.idwr.idaho.gov/files/projects/espam/browse/ESPAM22_Reports/Scenarios/CurtScen22_FinalwApp.pdf
  - Use average monthly ET and precipitation from WY2009-WY2018 instead of average annual values
- Analysis of municipal curtailment continues to use methods described in 2015 IDWR staff memo for Rangen delivery call (Sukow, 2015)
  https://idwr.idaho.gov/wp-content/uploads/sites/2/legal/CM-MP-2014-007/CM-MP-2014-007-20150123-Staff-Memo-Cities-2nd.pdf
  - Five-year average pumping rates within ACGW are updated each year based on reported annual pumping volumes
- Curtailment for April forecast begins ~ May 1
- Curtailment priority date revision for July forecast goes into effect ~ July 16 if April DS > July DS
- Curtailment priority date revision for July forecast goes into effect ~ August 1 if April DS < July DS
- Curtailment priority date revision for Time of Need (mid-August) forecast goes into effect ~ September 1
- Target for transient calculation is a modeled benefit at near Blackfoot to Minidoka equal to DS volume accruing between DS forecast date and September 30
- Earliest curtailment priority date is junior to October 11, 1900 (TFCC and NSCC natural flow water rights)



Comparison of priority dates calculated for April DS forecasts (May 1 curtailment)



Comparison of priority dates calculated for April DS forecasts (May 1 curtailment)

Predicted response to May 1 curtailment of water rights junior to October 11, 1900

Predicted response to May 1 curtailment of water rights junior to October 11, 1900

Transient analyses for 2021 shortfall volumes

- April DS forecast = 40,500 AF
  - Curtail junior to **January 11, 1971** starting May 1
    - May 1 – Sep 30 predicted response = 40,500 AF
- July DS forecast = 170,000 AF
  - Increase curtailment to junior to **October 11, 1900** starting August 1
    - Jul 1 – Sep 30 predicted response = 44,400 AF
- Time of Need DS forecast = 142,700 AF
  - Maintain curtailment junior to **October 11, 1900**
    - Aug 16 – Sep 30 predicted response = 27,400 AF
- Carryover shortfall forecast = 64,600 AF
  - Curtail junior to **April 19, 1961** starting January 1
    - Jan 1 – Sep 30 predicted response = 64,700 AF

Transient analysis for 2021 carryover shortfall

- Calculation target is volume accruing between date of curtailment and September 30 of the next irrigation season
- Carryover shortfall forecast = 64,600 AF
  - Curtail junior to **April 19, 1961** starting January 1
    - Jan 1 – Sep 30 predicted response = 64,700 AF

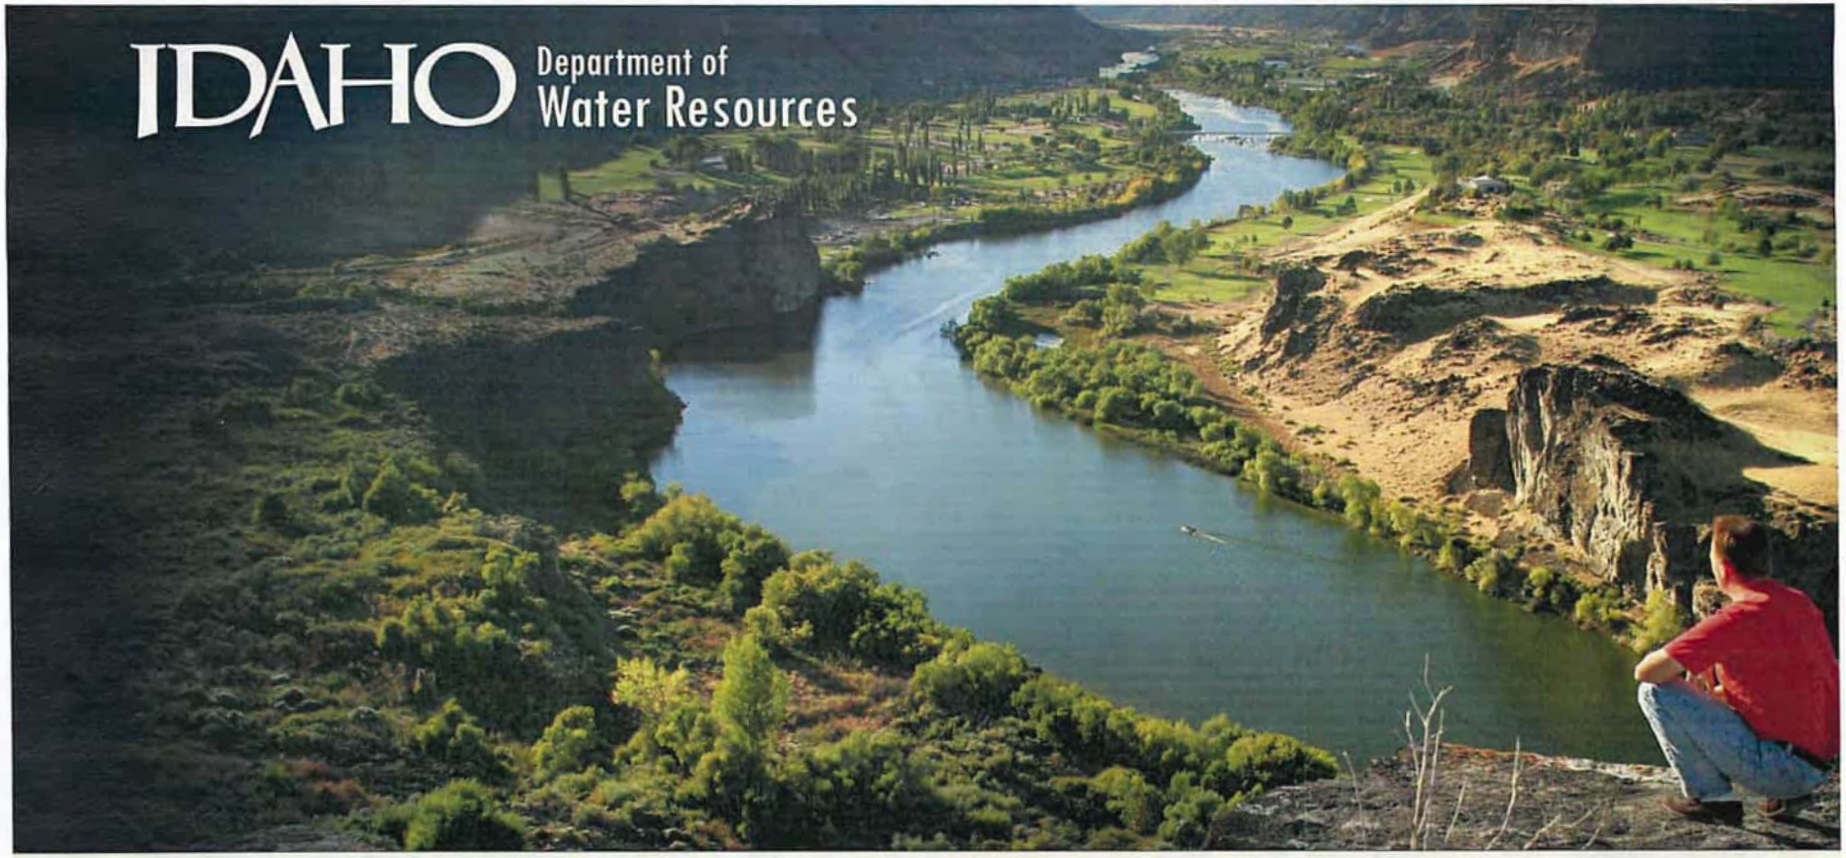
Transient analyses for 2022 shortfall volumes

- April DS forecast = 162,600 AF
  - Curtail junior to **October 11, 1900** starting May 1
    - May 1 – Sep 30 predicted response = 97,700 AF
- July DS forecast = 52,600 AF
  - Decrease curtailment to junior to **March 13, 1981** starting July 16
    - Jul 1 – Sep 30 predicted response = 52,600 AF
- Time of Need DS forecast = 132,100 AF
  - Increase curtailment to junior to **October 11, 1900** starting September 1
    - Aug 16 – Sep 30 predicted response = 27,200 AF

Comparison of priority dates calculated using transient and steady state analyses

Forecast	Steady state date	Transient date	Steady state acres	Transient acres
April 1, 2021	1990	1/11/1971	~30,000	357,000
July 1, 2021	7/18/1979	10/11/1900	130,300	941,400
August 15, 2021	1981	10/11/1900	~110,000	941,400
Final net DS	1976	10/11/1900	~200,000	941,400
Carryover 2021	6/29/1985	4/19/1961	55,300	539,700
April 1, 2022	12/25/1979	10/11/1900	124,700	941,400
July 1, 2022	3/12/1989	3/31/1981	39,300	104,700
August 15, 2022	3/25/1981	10/11/1900	105,000	941,400

Range of priority dates using steady state simulations:
1976 – 1990 (30,000 to 200,000 acres)



Range of priority dates using transient simulations:
1900 – 1981 (105,000 to 940,000 acres)

Conclusions

- Steady state simulations are appropriate for evaluating the impact of aquifer stresses that have been applied for decades (i.e. groundwater pumping, continuous curtailment to same date every year)
- Transient simulations are appropriate to evaluate the impacts of aquifer stresses applied for short periods of time (i.e. short-term curtailments with varying priority dates)
- Steady state simulations of continuous curtailment do not simulate the short-term curtailments prescribed in the SWC methodology
- Transient simulations better simulate the short-term curtailments prescribed in the SWC methodology

Conclusions

- Short-term curtailments in response to in-season predictions of DS are inadequate to provide water during the time of need for several of the shortfall volumes predicted in 2021-2022
- Curtailments sufficient to provide water during the time of need would also provide water to reduce shortfalls in future dry years, but would result in additional flow past Milner in future wet years

Proposed Modification to Method for Determining Reasonable In-Season Demand for the Surface Water Coalition:

Irrigated Acres For SWC Members

EXHIBIT 13
Matthew Anders, P.G.
5/12/23
M&M Court Reporting Service
Reported by: Andrea Check

Presented to the SWC Methodology Technical Working Group by Matt Anders

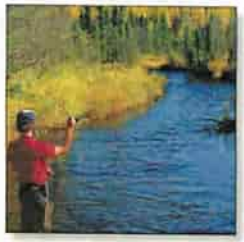
February 19, 2015

Settlement Document Subject to I.R.E. 408

Irrigated Acres

- Goal: Calculate injury based on the number of acres irrigated by the SWC.

- Water Right
  - "This right is limited to the irrigation of 56,392 acres within the place of use described above in a single irrigation season."
  - Permissible Place of Use (PPU) allows irrigation companies flexibility to move water around and remove acres from irrigation and add them back later.



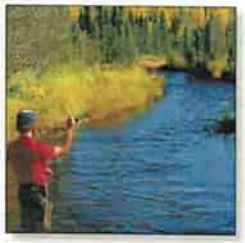
- In any given year, there is the potential for irrigation of less than the decreed acres.

Irrigated Acres

- Summary of irrigated acres:

SWC Member	2005-2007 SPF	2012 Partial Decrees	2013 SWC Submitted Shapefiles	2013 RISD
A&B		14,637 (2006 PD = 15,924)		15,924
AFRD2		62,361		62,361
Burley	44,715	47,643	46,084	44,715
Milner		13,335		13,335
Minidoka	70,144	75,093	74,112	70,144
NSCC		154,067		154,067
TFCC	183,589	196,162	194,778	183,589

Wildman Decision 2014



- http://idwr.idaho.gov/files/legal/CV-2010-382/CV-2010-382_20140926_Judgment.pdf
- Pg. 41: "if the Department is going to administer to less than the full amount of acres set forth on the face of the Coalition's Partial Decrees, such a determination must be supported by clear and convincing evidence".

IDAHO Department of Water Resources

IDWR

Shapefiles Submitted by SWC in 2013

- Non-irrigated urban areas, farmsteads, and subdivisions
- Overlaps and gaps
- Registration
- Land irrigated with supplemental GW is not segregated
- Examples in ArcMap…

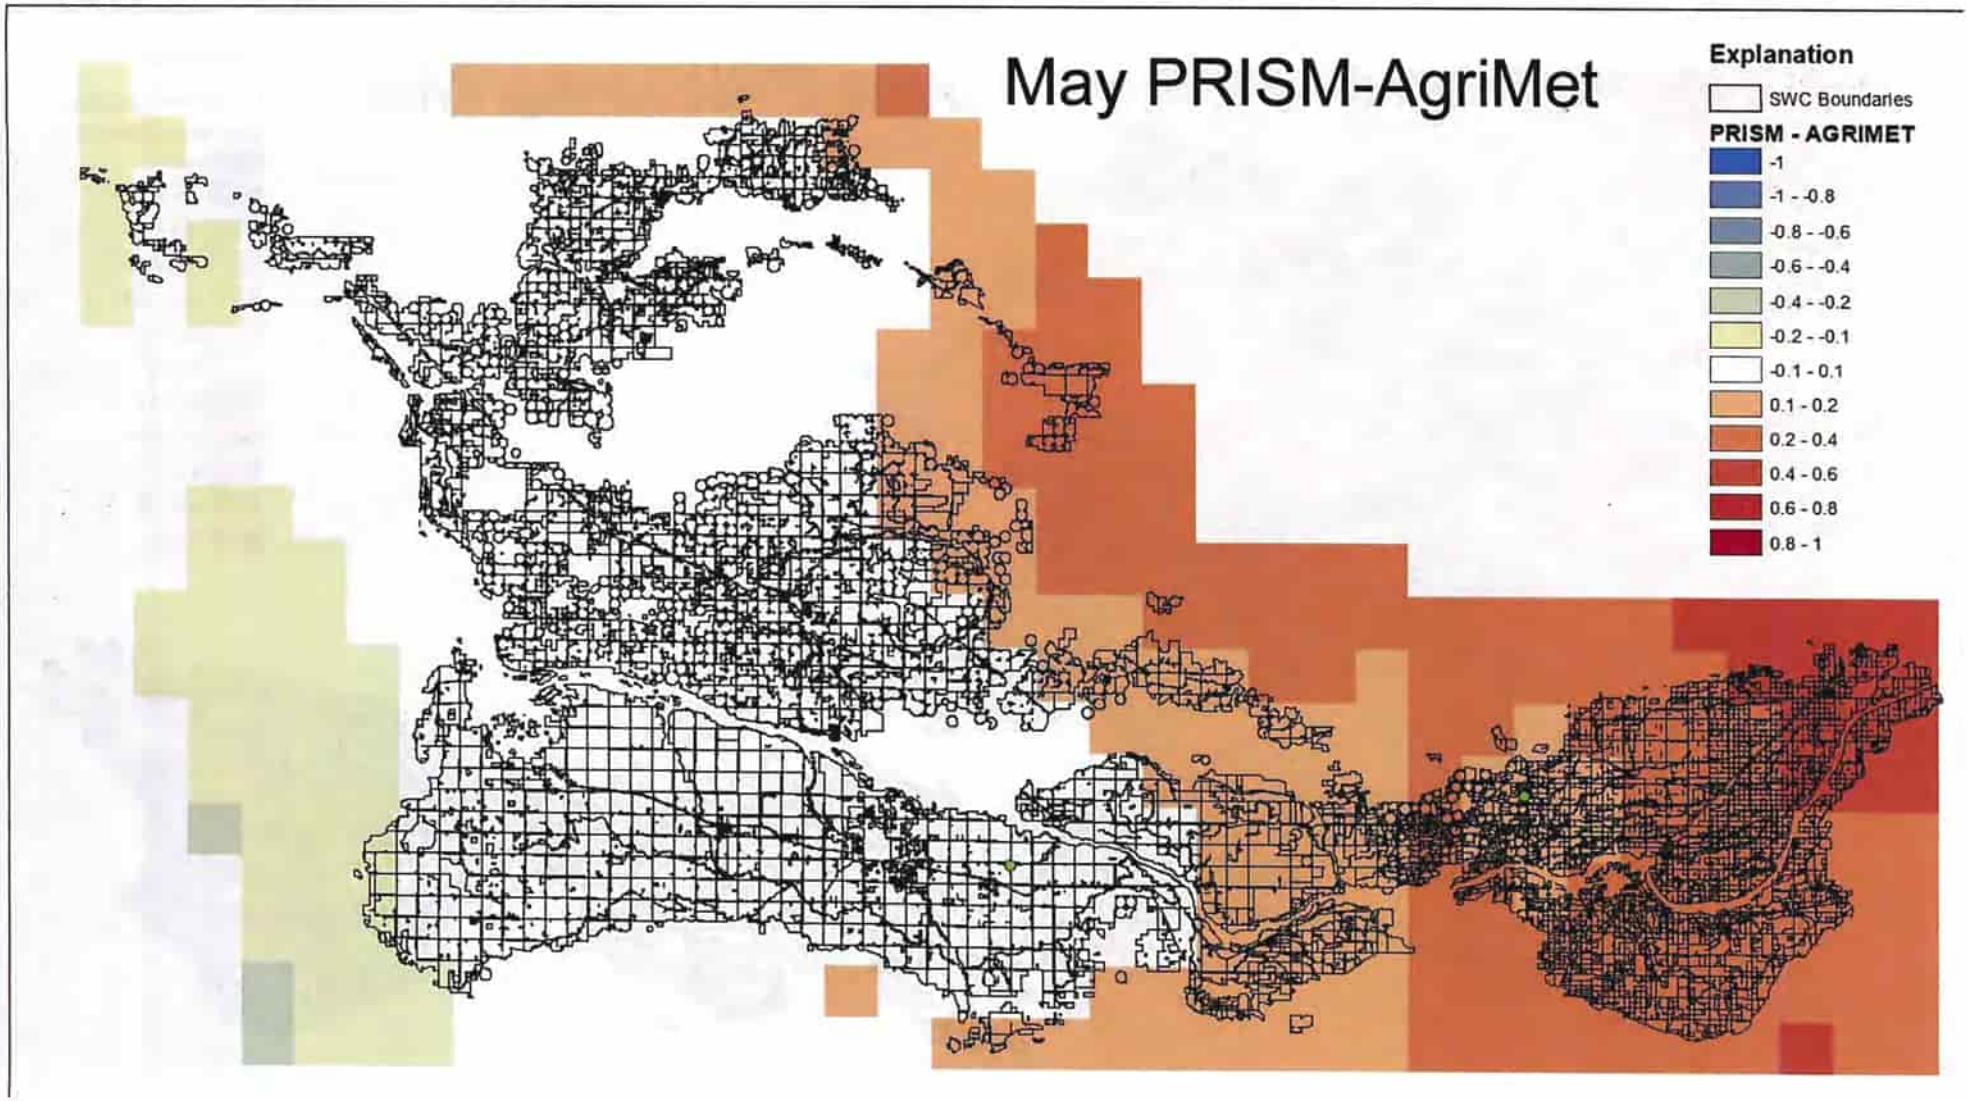
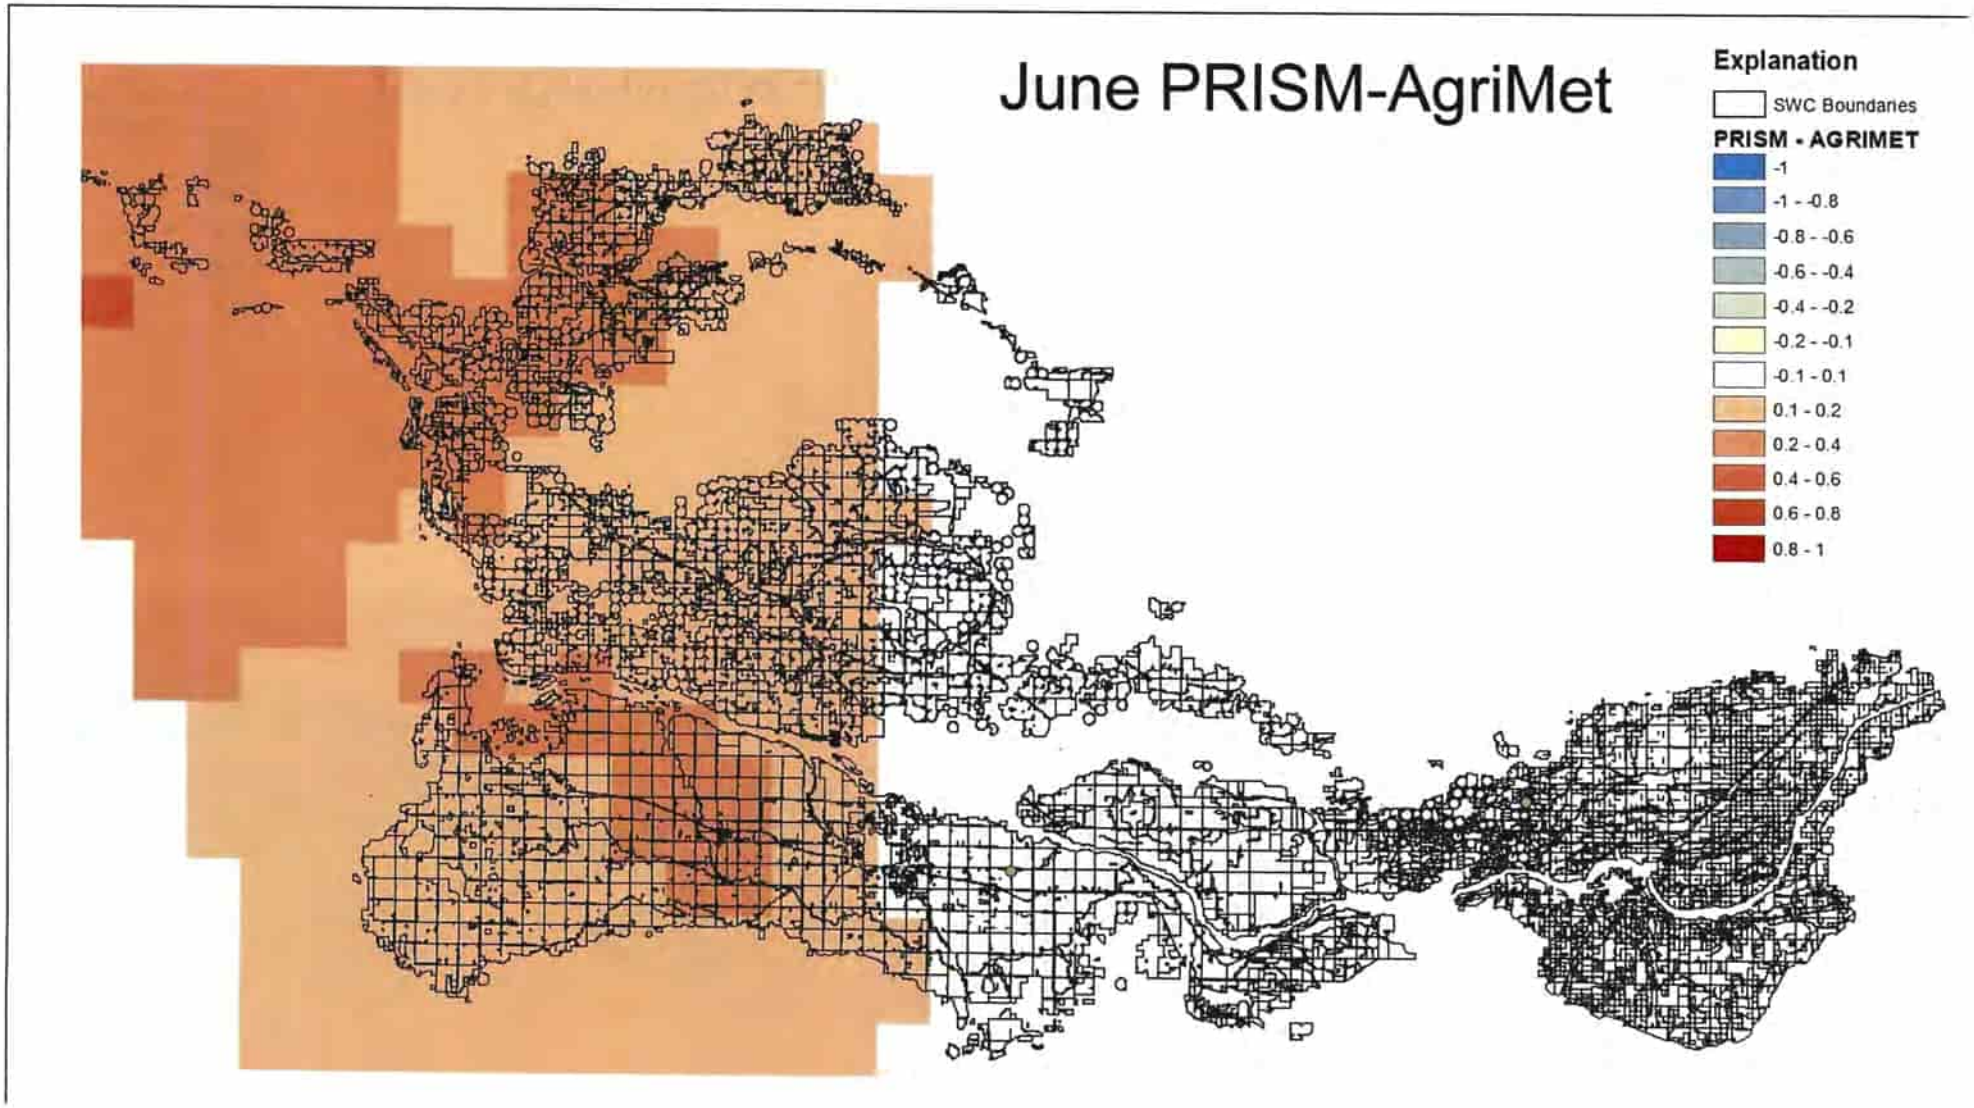
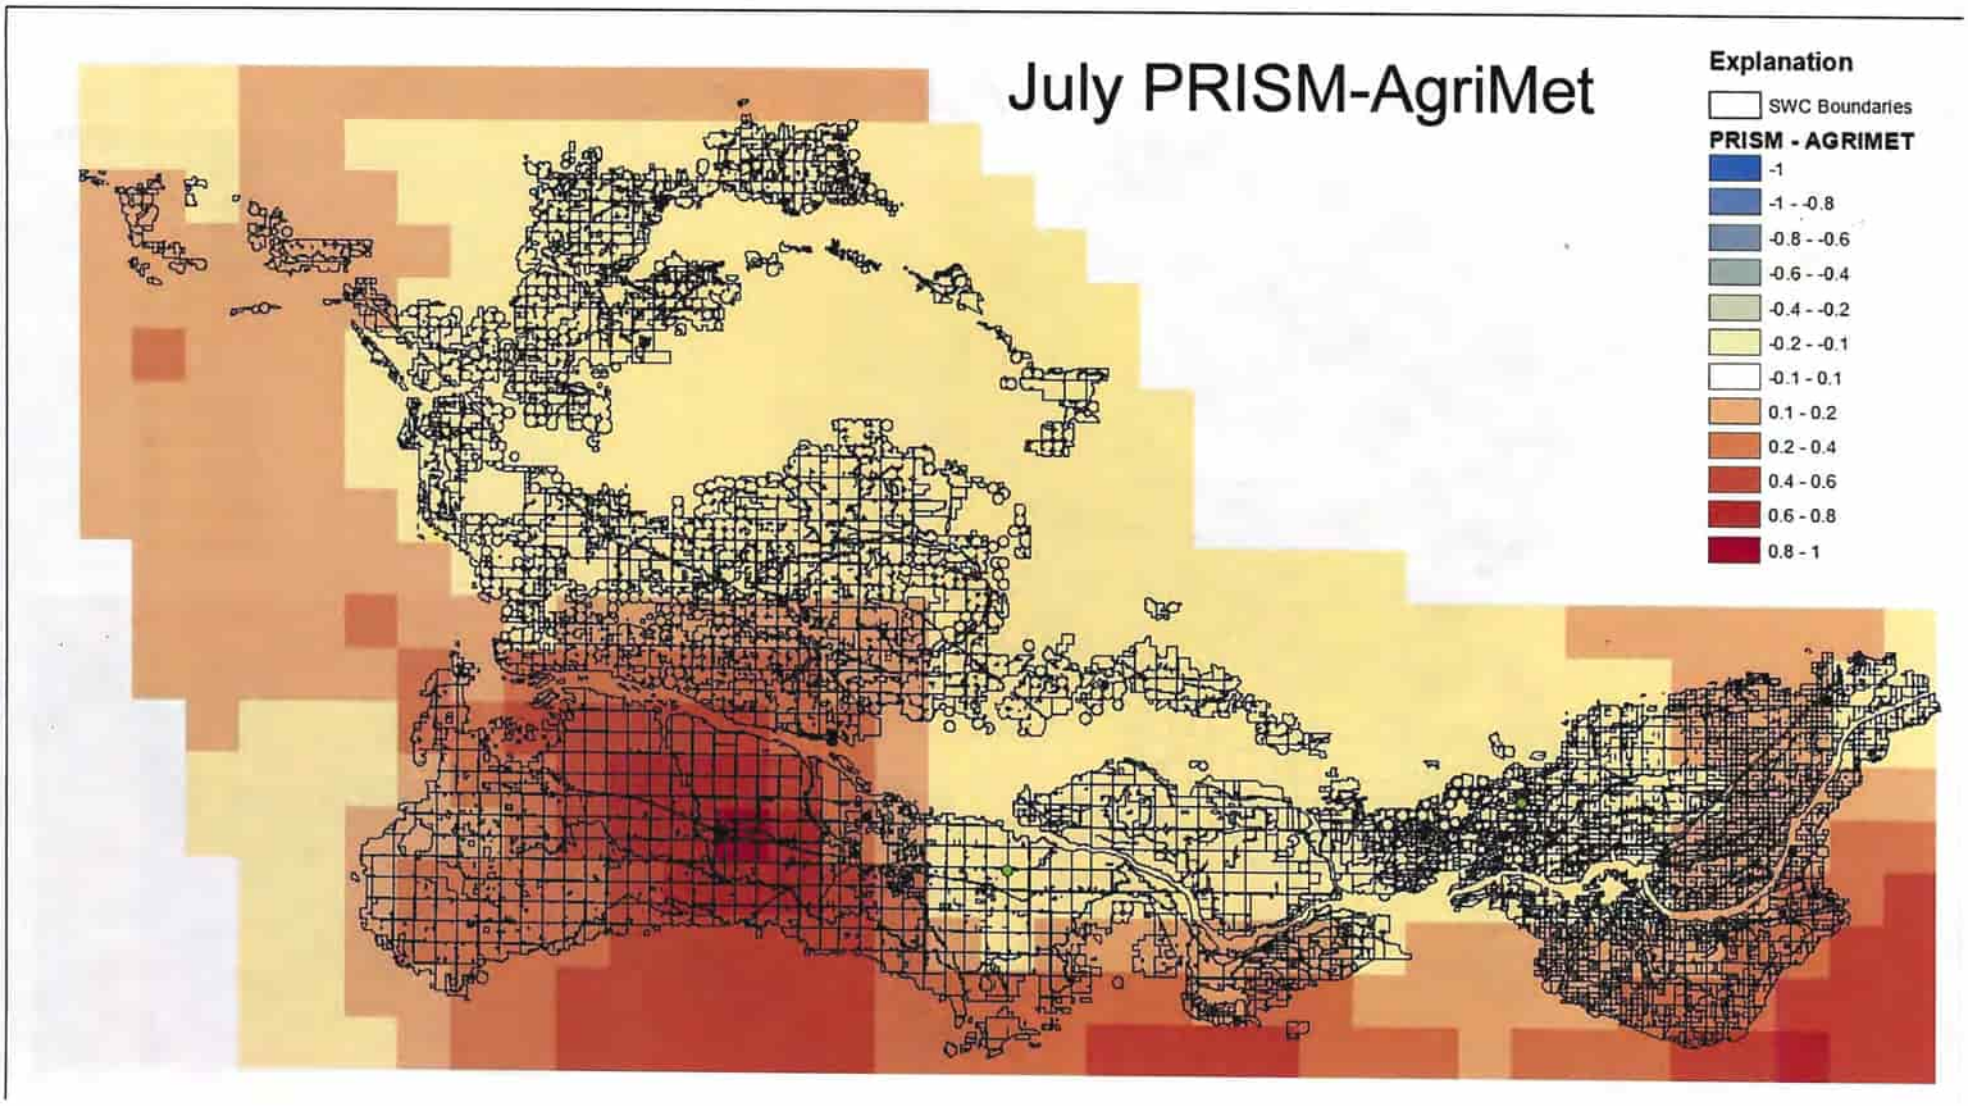
PRISM – AgriMet Difference Analysis for 2021



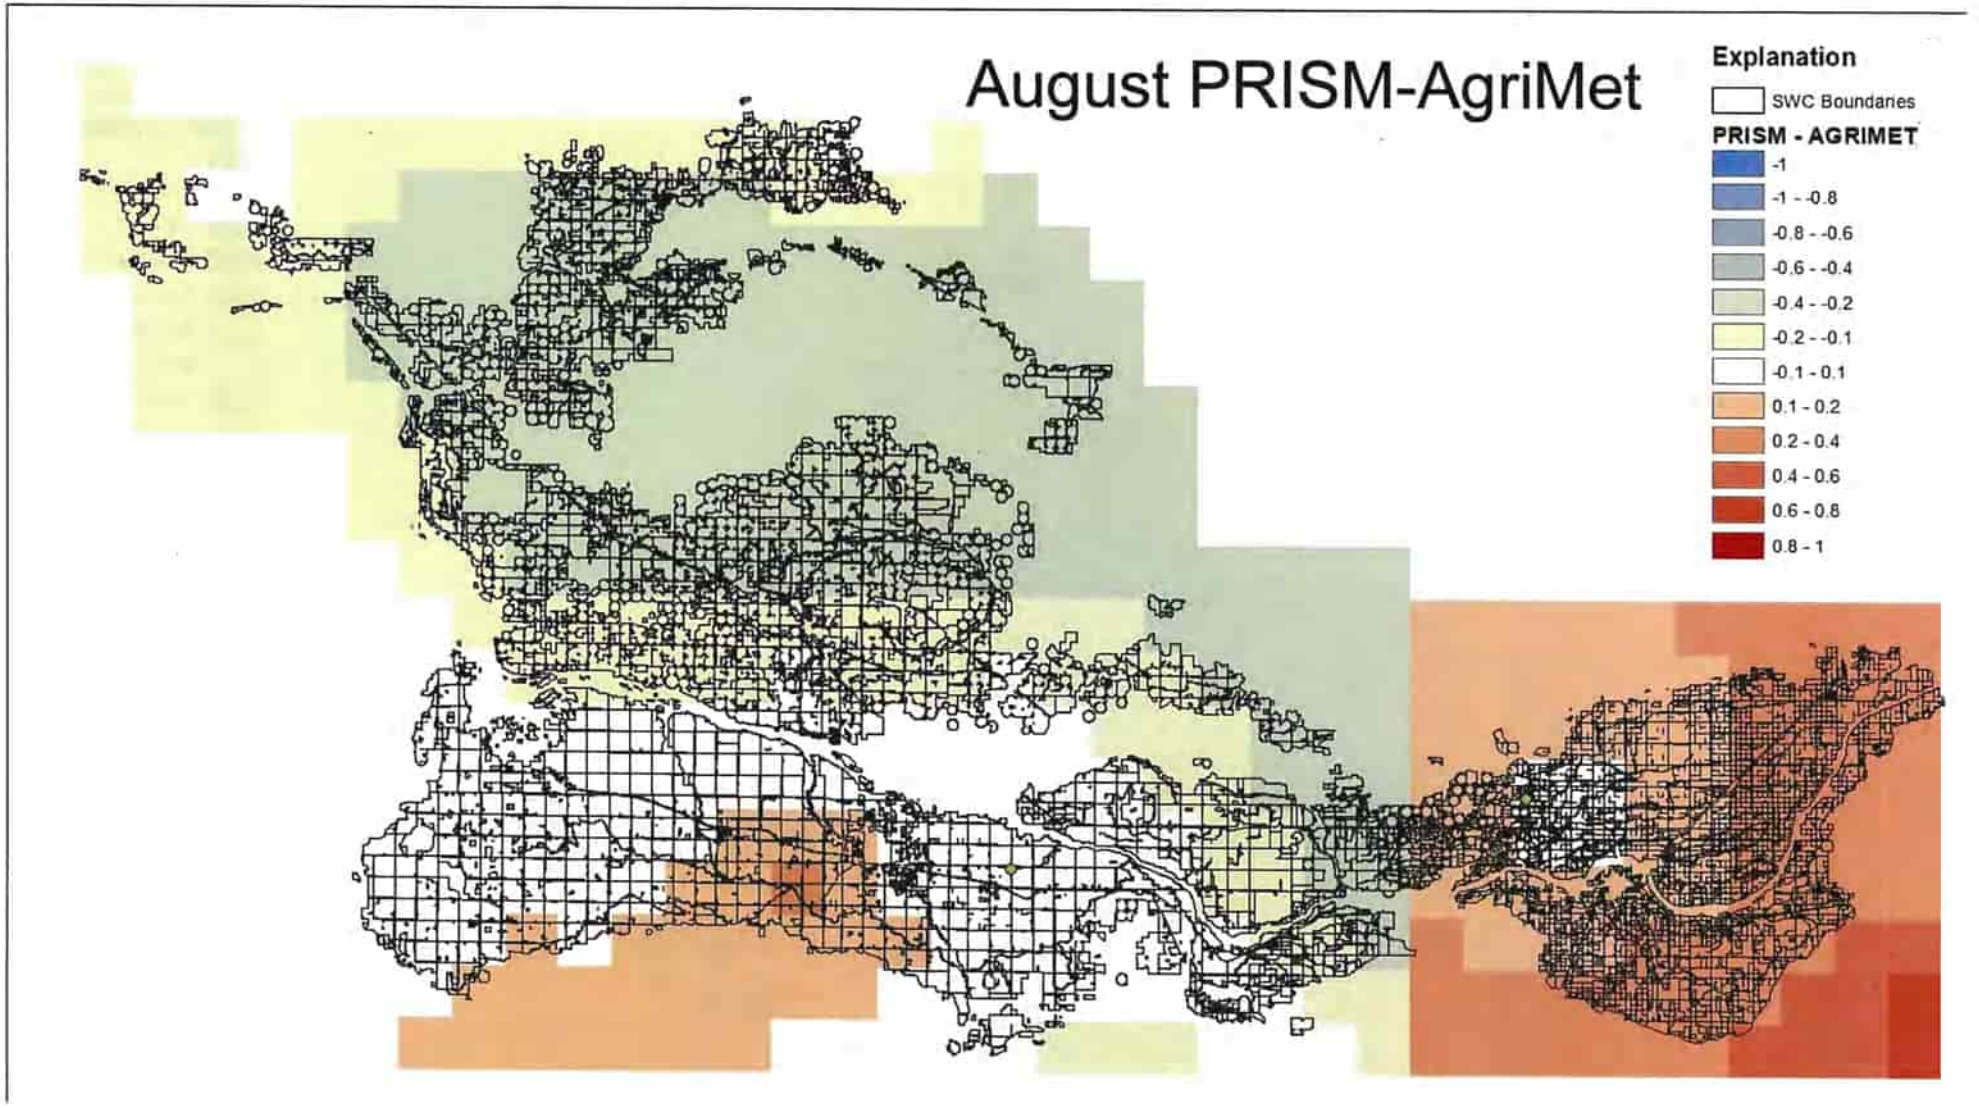
IDAHO Department of Water Resources



WATER RESOURCES



PRISM – AgriMet Difference Analysis for 2021



- Value (in inches) represent the difference between Effective precipitation from PRISM minus Effective Precipitation from AgriMet
- Same Effective precipitation method was used for both methods
- Twin Falls AgriMet was included for:
  - TFCC, AFRD2, NSCC, Milner
- Rupert AgriMet was included for:
  - A&B, Burley, MID
- Negative value in the graph below indicates Agrimet Effective precipitation was higher and would therefore decrease Crop Water Need more than PRISM for that month
- White background indicates the difference was between -0.1 and 0.1 inches

IDAHO Department of Water Resources

WATER RESOURCES

SWC Irrigated Acres

Current Method Crop Water Need

$CWN_{crop} = (ET_{crop}$ - Effective Precipitation) * $Acres_{crop}$

- AgriMet ET
- Daily data from Rupert & Twin Falls stations.

- AgriMet Precipitation
- Daily data from Rupert & Twin Falls stations.
- Calculate monthly effective precipitation.

- USDA Crop Data Layer (CDL)
- Remove data speckling and assign the majority crop in each polygon.
- Remove non-irrigated land from CDL using the IDWR Irrigated Lands Dataset.
- Clip CDL to SWC service areas.
- Determine the 3-year average crop mix percentage
- Acres of Each Crop = Crop Mix % * Acres From Methodology

IDAHO Department of Water Resources

WATER RESOURCES

Proposed Method NRT METRIC Crop Water Need

CWN = (ET - Effective Precipitation) * Acres

- NRT METRIC
- Remove non-irrigated land
- Normalize "ET – Effective Precipitation" to AF/Acre for each SWC member

- Irrigated acres from methodology

- Oregon State University Prism Precipitation
- Calculate monthly effective precipitation

WATER RESOURCES

Example – Non-Irrigated Acres Removed From TFCC

Methodology Reference

- Irrigated Acres (Page 35 of Methodology)
  - Step 1:
    - Department staff will review submitted shapefiles and modify them as necessary to ensure that:
      - (1) the total acreage count does not exceed the decreed number of acres;
      - (2) all of the irrigated land is located within the decreed place of use; and
      - (3) acres are not counted more than once due to overlapping polygons within a shapefile or between shapefiles submitted by different SWC members.
    - Because the SWC members can best determine the irrigated acres within their service area, the SWC should be responsible for submitting the information to the Department.
      - If this information is not timely submitted, the Department will determine the total irrigated acres based upon past cropping patterns and current satellite and/or aerial imagery.
      - If a SWC member fails or refuses to identify the number of irrigated acres within its service area by April 1, the Department will be cautious about recognizing acres as being irrigated if there is uncertainty about whether the acres are or will be irrigated during the upcoming irrigation season.

Re: Response to February 21, 2013 Letter (Step 1 Methodology Order)

Dear Director Spackman:

This letter responds to your February 21, 2013 to our clients, A&B Irrigation District, Burley Irrigation District, Milner Irrigation District, North Side Canal Company, and Twin Falls Canal Company.

Based upon a review of the information used with *Second Amended Final Order Regarding Methodology for Determining Material Injury to Reasonable In-Season Demand and Reasonable Carryover* ("Methodology Order"), it is our understanding IDWR used the following acreage amounts for the Crop Water Need calculation last year.[1]

A&B	15,924	(Director's Report)
BID	44,715	(Ex. 4300)
Milner	13,335	(Director's Report)
NSCC	154,067	(Director's Report)
TFCC	183,589	(Ex. 4310)

[1] Our clients contest the Methodology Order and its application and reserve all rights as to its legal basis and application. District Court cases on judicial review are currently stayed pending a final decision from the Idaho Supreme Court in the Surface Water Coalition Delivery Call case (Consolidated Docket No. 38191-2010).

Exh. No. 29
Date 5-25-23
Name Kay Barlogi
M & M Court Reporting

All of the natural flow water rights for the above entities that identify the number of authorized acres to irrigate within their respective project boundaries have been decreed since the issuance of the Methodology Order in June 2010. Accordingly, the Director is required to use the elements of the partial decrees instead of the Director's Reports for purposes of water right administration. I.C. §§ 42-607; 1417. For A&B, Milner, and NSCC, the total irrigated acreage number is the same. Dave Shaw has conferred with the managers for A&B, Milner, and NSCC, and has reviewed the shape files underlying the partial decrees. Based upon a review of the shape files with the most recent aerial imagery (2011), and confirming a review of the expected irrigated area within each project with the managers, the decreed irrigated acreage has not varied by more than 5% from the existing electronic shape file used last year.

For BID, the Methodology Order relies upon Ex. 4300 (SPF Engineering Report, 12/29/05). That report alleged that 40% of the "miscellaneous" lands within BID were "non-irrigated" based upon a review of 1987 and 2004 imagery. Dave Shaw performed a field verification of these areas in 2007 showing the errors in this calculation. Ex. 8190 (Table 4, pp. 10-11). The Director should correct this error for purposes of the 2013 irrigated acreage ("These amounts may, of course, change as acreage is removed from irrigation or possibly added back in."). R. 7000; Methodology Order at 4. These are just some of the examples that were found to be in error. BID further prepared a GIS shapefile based upon 2011 aerial imagery. Based upon a review of that information by BID's manager and Dave Shaw, the decreed irrigated acreage has not varied by more than 5% from the decreed acreage.

For TFCC, the Methodology Order relies upon Ex. 4310 (SPF Engineering Report, 3/20/07). That report alleged various areas were "non-irrigated" based upon a review of 1987 and 2004 imagery, and site visits to 11 parcels in Aug/Sept. 2006. Brockway Engineering consulted TFCC personnel and performed field verifications in January 2006 and identified errors in the SPF Engineering Report analysis. Ex. 8190 (Table 1, pp. 3-4). Accordingly, the areas delineated as "non-irrigated" in Ex. 4310 are not accurate. The Hearing Officer accepted Brockway Engineering's rebuttal to the SPF Report and concluded that only "6,600 acres claimed by TFCC are not irrigated." R. 7100. TFCC claimed 201,560.4 acres in its water right claims in the SRBA. TFCC's partial decrees authorize the irrigation of 196,162 acres. Accordingly, there is no basis for the Director to use the 183,589 acres alleged in the SPF Engineering Report. Moreover, Dave Shaw has completed a review of IDWR's SRBA shapefile for TFCC, compared to aerial imagery from 2011 and found the acreage variation was less than 5% of the decreed acreage. That information is included herein on the attached CD and should be used for 2013.

Finally, the Director's Crop Water Need relies upon NASS crop data (average 1990-2008). Dave Shaw has compiled current NASS data from the various counties from 2011. Since that review the 2012 NASS data have become available. Based upon this review and confirmation with the managers, the cropping pattern in 2013 is expected to be similar to that experienced last year and in 2011. The Director should use the most current NASS data available from the NASS "CropScape" website, http://nassgeodata.gmu.edu/CropScape/.

If you have any questions please contact me at (208) 733-0700.

Sincerely,

BARKER ROSHOLT & SIMPSON LLP

Re: 2014 Conjunctive Administration (Step 1 Methodology Order)

Dear Director Spackman:

We are writing on behalf of our clients A&B Irrigation District, Burley Irrigation District, Milner Irrigation District, North Side Canal Company, and Twin Falls Canal Company.

Based upon letters to ground water users (January 28th and March 4th) it appears you will rely upon the *Second Amended Final Order Regarding Methodology for Determining Material Injury to Reasonable In-Season Demand and Reasonable Carryover* ("Methodology Order") for purposes of conjunctive administration this year.[1] If so, our clients contest any orders or administration that does not comply with the Idaho Supreme Court's recent decision *A&B Irr. Dist. et al. v. Spackman*, 315 P.3d 828 (2013). We have yet to receive any information confirming how you intend to proceed this year.

However, with respect to the prior methodology and the Step 1 requirement to confirm irrigated acreage for the year, our clients adopt and resubmit the letter that was delivered to you last year for purposes of 2014 administration. *See Attachment.*

As noted last year, all of our clients' decreed natural flow water rights identify the number of authorized acres to irrigate within their respective project boundaries. Accordingly, the Director is required to use the elements of the partial decrees for purposes of water right administration. I.C. §§ 42-607; 1417.

[1] Our clients contest the Methodology Order and its application and reserve all rights to challenge that decision and its application. The Methodology Order and other orders concerning its implementation in prior years are currently on appeal to the Gooding County District Court (Consolidated Case No. CV-2010-382).

Moreover, all clients have confirmed that the expected irrigated area within each project this year has not varied by more than 5% from the existing information (electronic shape files) that were submitted to you and referenced last year. The number of irrigated acres identified by existing shape files on file with the SRBA Court or as submitted to you last year is as follows: A&B – 15,924; BID – 46,083; Milner – 13,335; NSCC – 154,067; TFCC – 194,778.

If you have any questions please contact me at (208) 733-0700.

Sincerely,

BARKER ROSHOLT & SIMPSON LLP

Re: Response to February 21, 2013 Letter (Step 1 Methodology Order)

Dear Director Spackman:

This letter responds to your February 21, 2013 to our clients, A&B Irrigation District, Burley Irrigation District, Milner Irrigation District, North Side Canal Company, and Twin Falls Canal Company.

Based upon a review of the information used with *Second Amended Final Order Regarding Methodology for Determining Material Injury to Reasonable In-Season Demand and Reasonable Carryover* ("Methodology Order"), it is our understanding IDWR used the following acreage amounts for the Crop Water Need calculation last year.[1]

A&B	15,924	(Director's Report)
BID	44,715	(Ex. 4300)
Milner	13,335	(Director's Report)
NSCC	154,067	(Director's Report)
TFCC	183,589	(Ex. 4310)

[1] Our clients contest the Methodology Order and its application and reserve all rights as to its legal basis and application. District Court cases on judicial review are currently stayed pending a final decision from the Idaho Supreme Court in the Surface Water Coalition Delivery Call case (Consolidated Docket No. 38191-2010).

All of the natural flow water rights for the above entities that identify the number of authorized acres to irrigate within their respective project boundaries have been decreed since the issuance of the Methodology Order in June 2010. Accordingly, the Director is required to use the elements of the partial decrees instead of the Director's Reports for purposes of water right administration. I.C. §§ 42-607; 1417. For A&B, Milner, and NSCC, the total irrigated acreage number is the same. Dave Shaw has conferred with the managers for A&B, Milner, and NSCC, and has reviewed the shape files underlying the partial decrees. Based upon a review of the shape files with the most recent aerial imagery (2011), and confirming a review of the expected irrigated area within each project with the managers, the decreed irrigated acreage has not varied by more than 5% from the existing electronic shape file used last year.

For BID, the Methodology Order relies upon Ex. 4300 (SPF Engineering Report, 12/29/05). That report alleged that 40% of the "miscellaneous" lands within BID were "non-irrigated" based upon a review of 1987 and 2004 imagery. Dave Shaw performed a field verification of these areas in 2007 showing the errors in this calculation. Ex. 8190 (Table 4, pp. 10-11). The Director should correct this error for purposes of the 2013 irrigated acreage ("These amounts may, of course, change as acreage is removed from irrigation or possibly added back in."). R. 7000; Methodology Order at 4. These are just some of the examples that were found to be in error. BID further prepared a GIS shapefile based upon 2011 aerial imagery. Based upon a review of that information by BID's manager and Dave Shaw, the decreed irrigated acreage has not varied by more than 5% from the decreed acreage.

For TFCC, the Methodology Order relies upon Ex. 4310 (SPF Engineering Report, 3/20/07). That report alleged various areas were "non-irrigated" based upon a review of 1987 and 2004 imagery, and site visits to 11 parcels in Aug/Sept. 2006. Brockway Engineering consulted TFCC personnel and performed field verifications in January 2006 and identified errors in the SPF Engineering Report analysis. Ex. 8190 (Table 1, pp. 3-4). Accordingly, the areas delineated as "non-irrigated" in Ex. 4310 are not accurate. The Hearing Officer accepted Brockway Engineering's rebuttal to the SPF Report and concluded that only "6,600 acres claimed by TFCC are not irrigated." R. 7100. TFCC claimed 201,560.4 acres in its water right claims in the SRBA. TFCC's partial decrees authorize the irrigation of 196,162 acres. Accordingly, there is no basis for the Director to use the 183,589 acres alleged in the SPF Engineering Report. Moreover, Dave Shaw has completed a review of IDWR's SRBA shapefile for TFCC, compared to aerial imagery from 2011 and found the acreage variation was less than 5% of the decreed acreage. That information is included herein on the attached CD and should be used for 2013.

Finally, the Director's Crop Water Need relies upon NASS crop data (average 1990-2008). Dave Shaw has compiled current NASS data from the various counties from 2011. Since that review the 2012 NASS data have become available. Based upon this review and confirmation with the managers, the cropping pattern in 2013 is expected to be similar to that experienced last year and in 2011. The Director should use the most current NASS data available from the NASS "CropScape" website, http://nassgeodata.gmu.edu/CropScape/.

Re: 2017 Conjunctive Administration (Step 1 Methodology Order)

Dear Director Spackman:

We are writing on behalf of our clients A&B Irrigation District, Burley Irrigation District, Milner Irrigation District, North Side Canal Company, and Twin Falls Canal Company in response to your February 2, 2017 letter concerning Step 1 of the Third Amended Methodology Order.

With respect to the Step 1 requirement to confirm irrigated acreage for the year, our clients adopt and resubmit the letter that was delivered to you for purposes of 2014 administration that is on file with you in this matter.[1] As noted in that letter, all of our clients' decreed natural flow water rights identify the number of authorized acres to irrigate within their respective project boundaries. Accordingly, the Director is required to use the elements of the partial decrees for purposes of water right administration. I.C. §§ 42-607; 1417.

Moreover, all clients have confirmed that the expected irrigated area within each project this year has not varied by more than 5% from the existing information (electronic shape files) that have been submitted to you in prior years.

The number of irrigated acres identified by existing shape files on file with the SRBA Court or as submitted to you in prior years is as follows: A&B – 15,924[2]; BID – 46,083; Milner – 13,335; NSCC – 154,067; TFCC – 194,778.

---

[1] Step 1 did not change for purposes of the various methodology orders.
[2] This is the number of acres associated with A&B's decreed natural flow surface water rights (1-14 et al.). The District is also delivering surface water to other District lands through "soft conversion" projects. *See Travis L. Thompson December 22, 2016 Letter to Director Spackman.*

If you have any questions please contact me at (208) 733-0700.

Re: 2020 Conjunctive Administration (Step 1 Methodology Order)

Dear Director Spackman:

We are writing on behalf of our clients A&B Irrigation District, Burley Irrigation District, Milner Irrigation District, North Side Canal Company, and Twin Falls Canal Company in response to your March 9, 2010 letter concerning Step 1 of the Third Amended Methodology Order.

With respect to the Step 1 requirement to confirm irrigated acreage for the year, our clients adopt and resubmit the letter that was delivered to you for purposes of 2014 administration that is on file with you in this matter.[1] As noted in that letter, all of our clients' decreed natural flow water rights identify the number of authorized acres to irrigate within their respective project boundaries. Accordingly, the Director is required to use the elements of the partial decrees for purposes of water right administration. I.C. §§ 42-607; 1417.

Moreover, all clients have confirmed that the expected irrigated area within each project this year has not varied by more than 5% from the existing information (electronic shape files) that have been submitted to you in prior years.

The number of irrigated acres identified by existing shape files on file with the SRBA Court or as submitted to you in prior years is as follows: A&B – 15,924[2]; BID – 46,083; Milner – 13,335; NSCC – 154,067; TFCC – 194,778.

---

[1] Step 1 did not change for purposes of the various methodology orders.
[2] This is the number of acres associated with A&B's decreed natural flow surface water rights (1-14 et al.). The District is also delivering surface water to other District lands through "soft conversion" projects. *See Travis L. Thompson December 22, 2016 Letter to Director Spackman.*

If you have any questions please contact me at (208) 733-0700.

Sincerely,

BARKER ROSHOLT & SIMPSON LLP

Re: 2022 Conjunctive Administration (Step 1 Methodology Order)

Dear Director Spackman:

We are writing on behalf of our clients A&B Irrigation District, Burley Irrigation District, Milner Irrigation District, North Side Canal Company, and Twin Falls Canal Company in response to your March 1, 2022 letter concerning Step 1 of the Third Amended Methodology Order.

With respect to the Step 1 requirement to confirm irrigated acreage for the year, our clients adopt and resubmit the letter that was delivered to you for purposes of 2014 administration that is on file with you in this matter.[1] As noted in that letter, all of our clients' decreed natural flow water rights identify the number of authorized acres to irrigate within their respective project boundaries. Further, NSCC recently submitted information regarding certain changes to its boundary, but it did not change the total irrigated acreage. Accordingly, the Director is required to use the elements of the partial decrees for purposes of water right administration. I.C. §§ 42-607; 1417.

Moreover, all clients have confirmed that the expected irrigated area within each project this year has not varied by more than 5% from the existing information (electronic shape files) that have been submitted to you in prior years.

[1] Step 1 did not change for purposes of the various methodology orders.

The number of irrigated acres identified by existing shape files on file with the SRBA Court or as submitted to you in prior years is as follows: A&B – 15,924[2]; BID – 46,083; Milner – 13,335; NSCC – 154,067; TFCC – 194,778.

If you have any questions please contact me at (208) 733-0700.

Sincerely,

BARKER ROSHOLT & SIMPSON LLP

Travis L. Thompson

Expert Report
Surface Water Coalition
Methodology Order

Gregory K. Sullivan, P.E.

Report Text

Section 1.0

P. 1, Paragraph 1, Line 6:	Deleted text "The Fifth Methodology Order amends and replaces the Fourth Methodology Order that was issued in 2016."
P. 1, Paragraph 2, Line 1:	Added text "The SWC members divert from the Snake River between Lake Walcott and Milner Dam under mostly senior natural flow water rights. They also have storage contracts in various upstream Bureau of Reclamation reservoirs. The following are the SWC members: • A&B Irrigation District ("A&B") • American Falls Reservoir District #2 ("AFRD2") • Burley Irrigation District ("BID") • Milner Irrigation District ("Milner") • Minidoka Irrigation District ("Minidoka") • North Side Canal Company ("NSCC") • Twin Falls Canal Company ("TFCC")"
P. 1, Paragraph 3, Line 1:	Added text "A more detailed summary of the SWC natural flow water rights and storage contracts is contained in SWE's 2007 expert report prepared for the 2008 hearing for the SWC delivery call (SWE 2007a)."
P. 2, Paragraph 1, Line 1:	"The Fifth Methodology Order made" should read "The Fifth Methodology Order amends and replaces the Fourth Methodology Order that was issued in 2016, and makes"
P. 2, Bullet 3, Line 2:	"Aquifer Groundwater Model" should read "Aquifer Model"
P. 2, Paragraph 2, Line 1:	"Hearing Officer Schroeder's ruling" should read "April 29, 2008, Order from Hearing Officer Schroeder (former Chief Justice of the Idaho Supreme Court)"
P. 3, Paragraph 4, Line 3:	"April-As Applied" should read "April As-Applied"
P. 3, Paragraph 2, Line 5:	"technical working groups" should read "technical working groups ("TWG")"
P. 3, Paragraph 2, Line 7:	"Technical Working Group ("TWG")" should read "TWG"
P. 4, Bullet 1, Line 5:	"A&B Irrigation District, American Falls Reservoir District #2, Burley Irrigation District, Milner Irrigation District, Minidoka Irrigation District,

North Side Canal Company, and Twin Falls Canal Company ["SWC"]" should read "the SWC"

P. 4, Bullet 6, Line 2: "Idaho Department of Resources" should read "Idaho Department of Water Resources"

Section 2.0

P. 6, Paragraph 2, Line 1:	"The IDWR supports the average combined SWC diversions during 2000-2021 of 3,200,389 AF described in paragraph 27 and the reported backup file is the diversion data" should read "The IDWR support for the average combined SWC diversions during 2000-2021 of 3,200,389 AF in paragraph 27 is provided in a backup file of diversion data"
P. 6, Paragraph 3, Line 2:	"Fourth Methodology" should read "Fourth Methodology Order"
P. 6, Paragraph 3, Line 3:	"show" should read "shows"
P. 6, Paragraph 5, Line 1:	Deleted text "difference between"
P. 7, Paragraph 4, Line 6:	Added text "(Idaho 1903)"

Section 3.0

P. 8, Paragraph 1, Line 9:	"IDWRIDWR" should read "IDWR"
P. 10, Paragraph 1, Line 1:	"systems." should read "systems (blue line)."
P. 10, Paragraph 4, Line 6:	"2008" should read "2008,"
P. 12, Paragraph 1, Line 4:	Deleted text "also"
P. 12, Paragraph 1, Line 7:	"It is not expected that the SWC members would at times operate at lower efficiencies than the reasonable values" should read "The SWC members may at times operate at lower efficiencies than the reasonable values when water supplies are plentiful"
P. 12, Paragraph 1, Line 10:	"than" should read "that"
P. 13, Section Header, Line 1:	"Fifth Methodology" should read "Fifth Methodology Order"
P. 13, Paragraph 1, Line 4:	"Firth" should read "Fifth"
P. 16, Paragraph 1, Line 5:	"shortfall" should read "shortfalls"

Section 4.0

P. 17, Paragraph 1, Line 1:	"April 29, 2008," should read "2008"
P. 17, Paragraph 1, Line 1:	Deleted text "(former Chief Justice of the Idaho Supreme Court)"
P. 17, Paragraph 2, Line 2:	"IGW A" should read "IGWA"
P. 17, Paragraph 2, Line 4:	"of75,152" should read "of 75,212"

P. 18, Inset Table:	Added highlights to methodology acres column for Burley, Minidoka, and TFCC
P. 18, Paragraph 3, Line 1:	Added text "for Burley, Minidoka, and TFCC"
P. 18, Paragraph 3, Line 2:	"proposed to be used" should read "used"

Section 6.0

P. 22, Paragraph 3, Line 1:	"right" should read "rights"
P. 22, Paragraph 4, Line 1:	"The Fifth Methodology asserts that it must now update" should read "IDWR now asserts in the Fifth Methodology Order that it must"
P. 22, Paragraph 4, Line 2:	"has" should read "it has"
P. 22, Paragraph 4, Line 3:	"halfmonth time step" should read "calibration using monthly stress periods and halfmonth time steps"
P. 23, Paragraph 2, Line 1:	"The Fifth Methodology asserts" should read "IDWR asserts in the Fifth Methodology Order"
P. 23, Paragraph 6, Line 1:	"The halfmonth timestep has" should read "Monthly stress period and halfmonth time steps have"
P. 23, Paragraph 6, Line 1:	"ESPAM 2.1" should read "ESPAM"
P. 23, Paragraph 6, Line 2:	"is not a new refinement" should read "are not new refinements"
P. 23, Paragraph 6, Line 2:	"Even with prior versions of ESPAM understanding the impact difference between steady-state modeling verses transient modeling was well understood by me and all members of the ESPAM modeling committee including the Department who frequently discussed and evaluated the different versions of the model." should read "Prior to ESPAM 2.1, the differences between steady-state modeling and transient modeling were well understood by IDWR and the ESHMC members and were frequently discussed during meetings."
P. 23, Paragraph 8, Line 3:	"the pre-moratorium" should read "pumping by pre-moratorium wells"
P. 24, Paragraph 1, Line 2:	"November 28, 2022" should read "November 28, 2022,"
P. 25, Paragraph 5, Line 4:	"November 28, 2022" should read "November 28, 2022,"

Section 7.0

P. 27, Bullet 3, Line 2:	"arbitrary, capricious, and unrealistic" should read "arbitrary and unreasonable"
P. 27, Bullet 3, Line 4:	"considered" should read "considered in computing the average annual diversions"
P. 27, Bullet 4, Line 2:	"monthly project efficiencies have declined." should read "project efficiencies of most SWC members have declined."

P. 27, Bullet 5, Line 1:	"conversions, advancements" should read "conversions and advancements"
P. 27, Bullet 5, Line 2:	Deleted text ", and reductions in irrigated area due to development and urbanization"
P. 27, Bullet 6, Line 1:	"Low" should read "Lower"
P. 28, Bullet 9, Line 1:	"show" should read "during the last 15 years show"
P. 28, Bullet 11, Line 1:	"crop" should read "SWC diversion"
P..28, Bullet 12, Line 7:	Added text "The monthly efficiency values for September should be used for October."
Section 8.0	
P. 30, Paragraph 1, Line 1:	Added text "The following information was relied upon in preparing this expert report."
P. 30, Paragraph 4, Line 1:	Added text "Idaho. 1903. Contract Between Idaho State Board of Land Commissioners and Twin Falls Land and Water Company. January 2, 1903."
P. 32, Paragraph 1, Line 4:	Added text ", and all references listed therein"
P. 32, Paragraph 3, Line 4:	Added text ", and all references listed therein"
P. 32, Paragraph 4, Line 1:	Added text "Sullivan, 2008a. Spronk Water Engineers, Inc. Expert Report Dated July 16, 2008 Prepared for the City of Pocatello. In the Matter of the Petition for Delivery Call of A&B Irrigation District for Delivery of Ground Water and for the Creation of a Ground Water Management Area, and all references listed therein."
P. 32, Paragraph 5, Line 1:	Added text "Sullivan, 2008b. Spronk Water Engineers, Inc. Expert Rebuttal Report Dated August 27, 2008 Prepared for the City of Pocatello. In the Matter of the Petition for Delivery Call of A&B Irrigation District for Delivery of Ground Water and for the Creation of a Ground Water Management Area, and all references listed therein."
P.32, Paragraph 6, Line 1:	Added text "Sullivan, 2008c. Spronk Water Engineers, Inc. Expert Sur-Rebuttal Report Dated September 16, 2008 Prepared for the City of Pocatello. In the Matter of the Petition for Delivery Call of A&B Irrigation District for Delivery of Ground Water and for the Creation of a Ground Water Management Area, and all references listed therein."

1.0 INTRODUCTION

On April 21, 2023, the Director of the Idaho Department of Water Resources ("IDWR") issued the *Fifth Amended Final Order Regarding Methodology for Determining Material Injury To Reasonable In-Season Demand and Reasonable Carryover* ("Fifth Methodology Order") describing procedures for IDWR's administration of a delivery call by the Surface Water Coalition ("SWC") that was originally placed in 2005 and has been administered ever since under what is generically referred to herein as the "SWC Methodology."

The SWC members divert from the Snake River between Lake Walcott and Milner Dam under mostly senior natural flow water rights. They also have storage contracts in various upstream Bureau of Reclamation reservoirs. The following are the SWC members:

- A&B Irrigation District ("A&B")
- American Falls Reservoir District #2 ("AFRD2")
- Burley Irrigation District ("BID")
- Milner Irrigation District ("Milner")
- Minidoka Irrigation District ("Minidoka")
- North Side Canal Company ("NSCC")
- Twin Falls Canal Company ("TFCC")

A more detailed summary of the SWC natural flow water rights and storage contracts is contained in SWE's 2007 expert report prepared for the 2008 hearing for the SWC delivery call (SWE 2007a).

On April 21, 2023, the IDWR Director also issued the *Final Order Regarding April 2023 Forecast Supply (Methodology Steps 1-3)* ("April As-Applied Order") describing the Director's implementation of Steps 1-3 of the Fifth Methodology Order in forecasting in-season water supply shortages to the SWC members in 2023. Based on the forecast shortages, the Director ordered that groundwater rights with priority dates junior to December 30, 1953, that are not part of an effectively operating mitigation plan will be subject to curtailment beginning on May 5, 2023.

Finally on April 21, 2023, the IDWR Director issued a *Notice of Hearing, Notice of Prehearing Conference, and Order Authorizing Discovery* that set a hearing on the SWC Methodology for June 6-10, 2023, in Boise, Idaho. According to a subsequent order on May 2, 2023, the deadline for submittal of expert reports from the parties is seven days before the first day of the hearing, which would be May 30, 2023.

The Fifth Methodology Order amends and replaces the Fourth Methodology Order that was issued in 2016, and makes several substantive changes to the SWC Methodology including the following:

- Change in the Baseline Year used to forecast the SWC member demands from an average of the member diversions during 2006, 2008, and 2012 to instead use the member diversions during 2018.
- Changes in the monthly project efficiencies for the SWC members that are used to compute monthly diversion demands for prior months when the shortage computations are updated mid-season (July), at the time of need, and after the irrigation season (November).
- Change in how the priority date for curtailment of groundwater rights is determined using the Eastern Snake Plain Aquifer Model ("ESPAM") from using steady-state curtailment runs to using transient curtailment runs.

It has been over 15 years since the 2008 hearing and April 29, 2008, Order from Hearing Officer Schroeder (former Chief Justice of the Idaho Supreme Court) that resulted in the Second Methodology Order issued in 2010. That was the last time the SWC Methodology was significantly scrutinized, and there are now 15 years of actual operating experience available to evaluate how the SWC Methodology has functioned. In addition, there have been numerous changed conditions over the last 15 years that may have affected surface water and groundwater use in the Upper Snake River Basin including the following:

- Urbanization of formerly irrigated parcels,
- Continued gravity to sprinkler conversions,
- Changes in crops,
- Canal lining,
- Advancements in remote sensing,
- Improved irrigation management,
- More and better measurements of water distribution and water use,
- More automation of irrigation facilities,
- Delivery of mitigation supplies to SWC members,
- Changes in WD01 accounting procedures, and
- Changes in WD01 rental pool rules.

Given these changed conditions and the substantive changes to the SWC Methodology included in the Fifth Methodology Order, now is an appropriate time to review all aspects of the SWC Methodology to determine whether the SWC members are operating with reasonable efficiencies and without waste, the SWC members are protected from material injury due to junior groundwater pumping, the groundwater users are protected

from excessive or undue curtailment and mitigation obligations, and the beneficial uses of the interconnected surface water and groundwater resources of the Snake River and the ESPA are maximized.

This expert report was prepared on behalf of the following entities who successfully petitioned to intervene in the SWC Methodology matter ("ESPA Cities"):

- City of Idaho Falls,
- City of Pocatello, and
- Coalition of Cities[1].

A map showing the locations of the ESPA Cities, the service area boundaries of the SWC members, and the ESPA Area of Common Groundwater is attached as **Figure 1-1.**

The compressed schedule established by the Director to complete discovery and prepare expert reports left insufficient time to perform all of the necessary work to thoroughly review the Fifth Methodology Order, the April As-Applied Order, and the historical operations of the SWC members during the last 15 years. The time limitations have necessitated that this report focus on certain key elements of the Fifth Methodology Order and eschew the more thorough review and analysis of the order that I would have performed had more time been made available prior to the expert report deadline and June hearing. Each section of this expert report describes my review, analysis, and expert opinions on a selected element of the Fifth Methodology Order. In addition to this expert report, I prepared and submitted two declarations in support of pre-hearing motions filed by the ESPA Cities. One of those declarations contains additional details regarding my prior work on the SWC Delivery Call and related matters.

My involvement in the SWC Delivery Call extends back to the original delivery call made by the SWC in 2005. In response to that delivery call, I compiled extensive data and analyzed the operations of the SWC irrigation systems. This included several weeks in the field observing diversion and conveyance facilities, irrigated farms, and irrigation application methods. In addition, I was present at the depositions of managers and staff of each of the SWC members regarding irrigation system operations, system losses and efficiencies, record keeping, and other related matters. Based on this information, I prepared analyses of the historical irrigation operations of each SWC member over the

[1] The Coalition of Cities includes the Cities of Bliss, Burley, Carey, Declo, Dietrich, Gooding, Hazelton, Heyburn, Jerome, Paul, Richfield, Rupert, Shoshone, and Wendell.

period from 1990 – 2006. The results of my work were documented in several expert reports and testimony presented at an IDWR hearing in February 2008.

Since the 2008 hearing regarding the SWC delivery call, I have reviewed the various amended methodology orders and the various as-applied orders concerning the SWC Methodology that have been issued over the years. In May 2010, I participated in a hearing on revisions to the SWC Methodology proposed by IDWR and testified at the hearing. I have also been involved in two technical working groups ("TWG") convened by IDWR to discuss potential changes to the SWC Methodology. The first was in early 2015 and the second in late 2022. I submitted comments to IDWR and the TWG in both instances.

I am incorporating into this Expert Report by reference the following expert reports and other information previously presented to IDWR and other parties:

- Franzoy, 2007. Franzoy Consulting, Inc. Expert Rebuttal Report Prepared in Rebuttal to Analyses and Conclusions of Experts for the Surface Water Coalition Dated November 7, 2007. Prepared for the City of Pocatello. In the Matter of the Request of Administration in Water District 120 and the Request for Delivery of Water to Senior Surface Water Rights by the SWC.
- Sullivan, 2007a. Spronk Water Engineers, Inc. Updated Expert Report Dated September 26, 2007 (revised December 2007). Prepared for the City of Pocatello. In the Matter of the Request of Administration in Water District 120 and the Request for Delivery of Water to Senior Surface Water Rights by the SWC.
- Sullivan, 2007b. Direct testimony of Gregory K, Sullivan, P.E. September 26, 2007 (Revised December 2007). Submitted on behalf of the City of Pocatello. In the Matter of Distribution of Water to Various Water Rights Held by or for the Benefit of the SWC.
- Sullivan, 2007c. Spronk Water Engineers, Inc. Expert Rebuttal Report. November 7, 2007 (Revised December 2007). Prepared for the City of Pocatello. In the Matter of the Request of Administration in Water District 120 and the Request for Delivery of Water to Senior Surface Water Rights by the SWC.
- Sullivan, 2015. Email to IDWR. Pocatello Comments on Draft Staff Memo. March 10, 2015.
- Sullivan and Netter, 2023. Spronk Water Engineers, Inc. Comments on behalf of the Coalition of Cities and the City of Pocatello on the Idaho Department of Water Resources Summary of Recommended Technical Revisions to the 4th Amended Final Order Regarding Methodology for Determining Material Injury to

Reasonable In-Season Demand and Reasonable Carryover for the Surface Water Coalition, by Kara Ferguson and Matt Anders on December 23, 2022. Comments Submitted on January 1, 2023.

- Sullivan, 2023a. Declaration of Gregory K, Sullivan, P.E. May 7, 2023. Case No. CM-DC-2010-0001.
- Sullivan, 2023b. Declaration of Gregory K, Sullivan, P.E. May 7, 2023. Case No. CM-DC-2010-001.

I stand by, reaffirm, and endorse my prior opinions and analyses described in the foregoing materials.

2.0 BASELINE YEAR

The Fifth Methodology Order changed the Baseline Year ("BLY") used to forecast the SWC diversion demands and reasonable carryover from the average diversions during 2006, 2008, and 2012 ("06/08/12") because the average diversions during these years reportedly no longer comply with a condition of the SWC Methodology that the BLY represent a year of above average diversions. Diversions of the SWC members reported in paragraph 27 of the Fifth Methodology Order indicated that the combined diversions of the SWC Members during 06/08/12 averaged 3,194,722 AF, which is 5,667 AF (0.18%) less than the combined diversions during 2000-2021 that averaged 3,200,389 AF. Annual diversions for the SWC members during 2000-2021 from the materials disclosed by Matt Anders (IDWR) during his deposition are summarized in **Table 2-1**.

The IDWR support for the average combined SWC diversions during 2000-2021 of 3,200,389 AF in paragraph 27 is provided in a backup file of diversion data disclosed by Matt Anders (IDWR) during his May 2023 deposition. However, the 06/08/12 average combined SWC diversions from the same data file are different than the figures reported in paragraph 27. The updated 06/08/12 combined diversions average 3,200,349 AF, which is only 40 AF (0.001%) less than the 2000-2021 average diversions.

The 06/08/12 average diversions in paragraph 27 are from the Fourth Methodology Order. Comparison of the backup data for the Fourth Methodology Order with the data disclosed by Mr. Anders shows that IDWR made some revisions to the prior data used for the Fourth Methodology Order. To be consistent, the same data should be used to compute and compare the 06/08/12 average and the 2000-2021 average.

To be sure, 3,200,349 AF is less than 3,200,389 AF, and so the 06/08/12 average is mathematically below average. However, this difference is insignificant and de minimis. Assuming a typical irrigation season from April 1 through October 31 (214 days), the combined diversions of the SWC members average approximately 15,000 AF/day. Therefore, the 40 AF that the 06/08/12 average diversions are below the 2000-2021 average represents less than five minutes of the combined amount that the SWC members divert on average.

The 40 AF that the 06/08/12 average diversions is below the 2000-2021 average is much less than the accuracy of the measuring flumes for the SWC member canals. Assuming the measurement accuracy of the SWC measuring devices is +/- 5%, the combined measurement error would be approximately 160,000 AF/year, which dwarfs the 40 AF that the 06/08/12 average diversions are below the 2000-2021 average. The Director's determination that the 06/08/12 average diversions no longer meet the above average

criteria appears arbitrary, and there is no clear and convincing evidence that this is the case.

Finally, the 22-year period from 2000-2021 that was used to compute the average diversions of the SWC members arbitrarily and conspicuously does not include the most recent year of diversion data, 2022. If the diversion data from 2022 are included, the average combined diversion for 2000-2022 is 3,189,818 AF, which is 10,530 AF less than the 06/08/12 average of 3,200,349 AF. In other words, the 06/08/12 average diversions are above the 2000-2022 average, and based on this comparison, 06/08/12 should still qualify as an above average figure.

The Director selected 2018 as the new BLY for the SWC Methodology because it reportedly met all of the BLY criteria, including being a year of above average diversions. The combined SWC member diversions during the proposed 2018 BLY (3,341,939 AF) are approximately 142,000 AF greater than the 06/08/12 average diversions (3,200,349 AF). So, the 40 AF (5,667 AF uncorrected) that the 06/08/12 average diversions are below the 2000-2021 average will translate into a much larger increase in the BLY combined diversions. In turn, this large increase will also result in substantially greater projected shortages to the SWC members under the Fifth Methodology Order than under the Fourth Methodology Order.

Review of the data in the Anders' spreadsheet indicates that the 06/08/12 average diversions are no longer above average because the diversions of six of the seven SWC members have actually increased since the Fourth Methodology Order was issued in 2016. Furthermore, the Anders spreadsheet does not factor in that the legally established delivery rate for TFCC is one cfs for each eighty acres of land, or five-eighths of a miner's inches for each acre of land (Idaho, 1903).

The diversion averaging period used for comparison to the BLY diversions in the Fourth Methodology Order was 2000 – 2014. Average combined diversions by the SWC members during 2000 – 2014 averaged 3,154,945 AF. During the recent 2015 – 2021 period, combined diversions by the SWC members increased by an average of 142,826 AF as shown in **Table 2-1**. IDWR performed no analyses to assess the reasonableness of the increased SWC member diversions since 2014 that prompted the need to change the BLY.

3.0 PROJECT EFFICIENCIES

Following the initial forecast of the shortages to the SWC members that is made in April based on the BLY estimate of the RISD, Step 6 of the Methodology Order specifies that the RISD will be updated approximately halfway through the irrigation season (~July) using the monthly figures for each SWC member of the Crop Water Need ("CWN") and the Project Efficiency ("PE") up to that point during the irrigation season, and monthly baseline demand figures from the BLY for the remaining months. Additional updates to the RISD's and shortages of the SWC members based on CWN and PE are made shortly before the Time of Need (Step 7) and following the end of the irrigation season (Step 9). The following is the formula that IDWR uses to compute the RISD at mid-season, Time of Need, and end of season (Fifth Methodology Order P. 16):

$$RISD_{milestonex_x} = \sum_{j=1}^{m}\left(\frac{CWN_j}{E_{p,j}}\right) + \sum_{j=m+1}^{7} BD_j$$

Where:

$RISD_{milestone_x}$ = reasonable in season demand at specified evaluation milestones during the irrigation season,
CWN = crop water need for month j,
E_p = baseline project efficiency for month j,
BD = baseline demand for month j,
j = index variable, and
m = upper bound of summation, equal to the month calculation occurs, where April = 1, May =2, … October = 7.

Monthly CWN values are computed for each SWC member based on Agrimet evapotranspiration data, precipitation data, and cropping information using the following formula (Fifth Methodology Order P. 14):

$$CWN = \sum_{i=1}^{n}(ET_i - W_e)A_i$$

Where,

CWN = crop water need
ET_i = consumptive use of specific crop type,
W_e = effective precipitation,
A_i = total irrigated area of specific crop type,
i = index variable representing the different specific crop types grown within the irrigation entity, and
n = upper bound of summation equal to the total number of different specific crop types grown within the irrigation entity.

The baseline project efficiencies for the monthly RISD calculation are computed for each SWC member for each month from April – October based on historical computations of CWN and historical monthly diversions adjusted to remove water not used for irrigation and to add water leased or rented to others. The following is the formula used to compute the monthly project efficiencies (Fifth Methodology Order P. 13):

$$E_p = \frac{CWN}{Q_D}$$

Where:

E_p = project efficiency,
CWN = crop water need, and
Q_D = irrigation entity diversion of water specifically put to beneficial use for the growing of crops within the irrigation entity.

In the Fourth Methodology Order, monthly project efficiencies for each SWC member for the preceding 8 years that were within two standard deviations of the average were averaged to compute the monthly values used in the RISD calculations. In the Fifth Methodology Order, the averaging period was changed to use data from the preceding 15 years. The following are the average monthly project efficiencies for each SWC member that will be used for the Fifth Methodology Order (P. 14):

Month	A&B	AFRD2	BID	Milner	Minidoka	NSCC	TFCC	Monthly Avg.
4	0.98	0.33	0.45	0.87	0.43	0.24	0.31	0.51
5	0.47	0.22	0.32	0.39	0.35	0.24	0.30	0.33
6	0.66	0.40	0.49	0.60	0.56	0.41	0.51	0.52
7	0.74	0.44	0.52	0.67	0.63	0.48	0.58	0.58
8	0.58	0.41	0.42	0.55	0.52	0.43	0.46	0.48
9	0.45	0.27	0.32	0.45	0.38	0.32	0.27	0.35
10	0.18	0.16	0.09	0.14	0.11	0.06	0.04	0.11
Season Avg.	0.58	0.32	0.37	0.52	0.43	0.31	0.35	

SWC Member Average Monthly Project Efficiencies from 2007-2021.[12]

Graphs illustrating monthly and annual average project efficiencies for 2007 – 2021 with values more than two standard deviations from the average removed are shown in **Figure 3-1** and **Figure 3-2**. **Figure 3-1** includes separate graphs of the monthly average efficiencies for each SWC member (solid black line) along with the seasonal average efficiency (dotted black line); both from the table in the Fifth Methodology Order. Also shown for comparison purposes is the reasonable annual efficiency for each SWC member

that I determined in 2007 as a part of my analysis of the SWC member irrigation systems (blue line). Additional discussion of the reasonable annual efficiencies is provided in Section 3.1 below.

Figure 3-2 shows the average monthly project efficiencies during 2007 – 2021 from the Fifth Methodology Order for each SWC member on the same graph. While the monthly project efficiencies for each SWC member vary from one another, the graph depicts a similar characteristic bell-shaped project efficiency curve for each SWC member. These characteristic curves are generally shifted up or down from one another due in part to differences in conveyance losses. A relatively long canal system like AFRD2 will generally have higher conveyance losses and lower project efficiencies than a relatively short canal system like A&B that will generally have lower conveyance losses and higher project efficiencies.

3.1 Reasonableness of Project Efficiencies

The monthly project efficiencies in the Fifth Methodology Order represent the actual efficiencies that result from dividing monthly CWN by monthly adjusted diversions for each SWC member. To my knowledge and per the deposition of Matthew Anders on May 12, 2023, IDWR has not attempted to assess whether the monthly project efficiencies are reasonable in comparison to industry standards for large, well-managed irrigation districts.

Reasonably attainable project efficiencies can be determined for each SWC member based on the conveyance efficiency in delivering water from the river heading to the farms (including allowances for reasonable operational waste) multiplied by a reasonable on-farm efficiency. This is essentially the procedure that IDWR used to analyze the delivery call of the Unit B pumping division of the A&B Irrigation District, and which resulted in the January 29, 2008, Order that found Unit B had not suffered injury because it was not short of water. In that analysis, IDWR determined that a reasonable project efficiency for the Unit B was 75% based on minimal conveyance losses (3.1% in 2006) and the following reported irrigation application efficiencies for sprinklers (Unit B is predominantly sprinkler irrigated):

47. Reported application efficiencies for various sprinkler irrigation systems are as follows:

Sprinkler System	Application Efficiency
stationary lateral (wheel or hand move)	60 – 75%
solid set lateral	60 – 85%
center pivot lateral	75 – 85%

Idaho Irrigation Water Conservation Task Force, 1994, p.38, and Report Regarding Evaluation of Irrigation Diversion Rates, Report to the SRBA District Court Prepared by the Idaho Department of Water Resources, January 14, 1999, p. 38.

This is also the same procedure that I employed in assessing the irrigation operations of the SWC members that is described in my expert reports and testimony presented at the 2008 hearing in the SWC Delivery Call.

Conveyance efficiencies for the SWC members are knowable and can be determined based on records of diversions and deliveries and based on the operational experience of the SWC managers and staff. Achievable on-farm irrigation efficiencies for various application methods (flood, furrow, sprinkler, drip, etc.) are also well established in the technical literature for the industry. The sprinkler efficiencies used in the A&B Order are examples of application efficiencies reported in the literature. Design irrigation application efficiencies generally represent the efficiencies that can be achieved assuming well managed irrigation systems. In my opinion, industry standard design efficiencies represent a level of performance that the SWC members should be expected to achieve before requiring curtailment of junior groundwater users because of computed irrigation water shortages.

My prior work on the SWC Delivery Call that is documented in the expert reports submitted along with testimony in 2008 found that several of the SWC members – A&B, AFRD2, Burley, Milner, and Minidoka – were generally operating with reasonable project efficiencies while others – NSCC and TFCC – were operating at less than reasonable levels.

I analyzed the operations of the SWC members during 1990 – 2006 and determined their actual project efficiencies for each year. In addition, reasonable project efficiencies were estimated based on reported conveyance efficiencies and industry standard application efficiencies weighted based on the mix of gravity and sprinkler irrigation at that time. A summary of the results from my 2007 expert report is provided in **Figure 3-3** along with averages of the monthly project efficiencies from paragraph 32 of the Fifth Methodology Order.

As seen in **Figure 3-3**, the maximum annual efficiencies of A&B, AFRD2, Burley, Milner, and Minidoka during the 1990 – 2006 period all reached the independently computed reasonable project efficiencies that were determined from analysis of the SWC systems. This validated the methodology used to determine the reasonable project efficiencies and showed that these five SWC members were capable of operating at the reasonable efficiency levels. The efficiencies lower than the maximums tended to occur in wetter years with more ample water supplies. The SWC members may at times operate at lower efficiencies than the reasonable values when water supplies are plentiful because it is generally easier to operate an irrigation system with an excess of diversions. However, the SWC should be held to a higher operational standard that they have shown they can achieve when junior groundwater users are being required to mitigate or be curtailed.

The maximum and average project efficiencies determined for NSCC and TFCC during 1990 – 2006 are well below the reasonable efficiencies determined for these two users based on their reported conveyance losses and irrigation application practices.

In my opinion, the analyses that I presented in expert reports and testimony during the 2008 Hearing on the SWC Methodology established reasonable annual project efficiencies that should be used in determining the SWC diversion requirements. These analyses showed that five of the seven SWC members had performed at the reasonable project efficiency levels, while NSCC and TFCC were operating at efficiencies well below reasonable levels. My opinions should not be construed as suggesting that the SWC members must operate at certain efficiency levels. However, when determining whether they are short of water, thus requiring mitigation or curtailment of junior groundwater users, reasonable project efficiencies using the procedures that I employed for my 2007 expert report should be used in determining the shortages.

Had there been time, I would have compiled the necessary information regarding the operations of the SWC members to update the operations analyses that I performed in 2007. Until these analyses can be updated, the reasonable project efficiency values that I determined in 2007 are reasonable for use in the SWC Methodology. This is because it is reasonable to expect that the reasonable project efficiencies for the SWC members should have increased during the last 15 years based on continued gravity to sprinkler conversions and general advancements in irrigation system operation and management.

Despite the expected advances in irrigation system efficiencies during the last fifteen years, comparison of the average project efficiencies determined by IDWR for 2007 – 2021 (black line in **Figure 3-3**) are lower than the average project efficiencies determined for 1990-2006 (red line in **Figure 3-3**). It appears that the declines in average project efficiencies since 2006 are due to these systems not being managed as well as they were in the past.

3.2 Proposed Adjustments to Fifth Methodology Order Efficiencies

If IDWR will not review and assess the reasonableness of the SWC member project efficiencies like it did in the A&B Delivery Call, and like I did in my expert reports and testimony presented in the 2008 hearing, I have developed an alternative proposal for assessing and revising the monthly project efficiencies used in the Fifth Methodology Order. This alternative builds upon the actual efficiencies that the SWC members have demonstrated they routinely achieve and conforms to the framework of the Fifth Methodology Order.

First, I offer the following opinions regarding the patterns of the actual monthly project efficiencies that are summarized in **Figure 3-1**:

- April: Efficiencies tend to be lower than mid-season efficiencies because of temporarily high conveyance losses during the initial period while the distribution system is "wetting." In addition, diversions may contribute to filling of soil moisture for crop use later in the season resulting in lower apparent efficiencies because the soil moisture filling is not included in the formula. Efficiencies are high for A&B and Milner, likely because their diversions tend to commence later in the month resulting in high CWNs use relative to diversions that are satisfied in part by soil moisture and possibly supplemental pumping.
- May: Similar to April, efficiencies tend to be lower than mid-season efficiencies because portions of the diversions are stored in soil moisture for later use. Also, spring precipitation events can reduce CWNs without a corresponding reduction in diversions.
- June-August: Efficiencies during June – August are highest when CWNs are peaking, and the systems are being operated most efficiently. The peak computed efficiencies may result from a portion of the CWNs being met from stored soil moisture and supplemental groundwater pumping.
- September: Efficiencies drop below mid-season values as CWNs decline due to harvesting and lower temperatures without a commensurate decline in diversions. In other words, the CWN declines are greater than the diversion declines.
- October: Efficiencies are typically very low because CWNs decline further due to harvesting and lower temperatures (including freezes) while relatively high diversions continue.

The low monthly average project efficiencies in April, May, September, and October can cause unreasonable spikes in the computed monthly diversion demand when the monthly

CWN is higher than average. This is because the actual efficiency in such a month would generally be higher than the monthly average value used in the demand calculation. This is demonstrated in the analyses presented below.

To further assess the project efficiencies used in the Fifth Methodology Order, graphs were prepared to assess the relationships between:

- Annual Adjusted Diversion vs. Annual CWN (**Figure 3-4**),
- Monthly Adjusted Diversion vs. Monthly CWN (**Figure 3-5 – Figure 3-11**),
- Annual Project Efficiency vs. Annual CWN (**Figure 3-12**), and
- Monthly Project Efficiency vs. Monthly CWN (**Figure 3-13 – Figure 3-19**).

The annual and monthly Adjusted Diversion vs. CWN graphs indicate that there is some correlation between adjusted diversion and CWN. The strength of the correlation indicated by the R-squared value varies by SWC member and by month. In addition to the scatter plots of adjusted diversion vs CWN, the graphs in **Figure 3-4 – Figure 3-11** also show the RISD predictor used in the Fifth Methodology Order (CWN/PE), plotted as a black line. In almost all graphs, the black line exhibits a greater slope than the linear trendline plotted through the data points. This indicates that the CWN/PE predictor is not a robust predictor of diversion demand. In many months, the monthly diversions appear relatively insensitive to changes in CWN. This is indicated in the plots with a relatively flat trendline juxtaposed with a relatively steep CWN/PE line.

The annual and monthly graphs of Project Efficiency vs. CWN in **Figure 3-12 – Figure 3-19** show moderate to strong positive correlations between project efficiency and CWN for the SWC members in many months. The months with moderate to strong PE to CWN correlations (R-squared > 50%) tend to be months with significant differences between the slopes of the diversion vs. CWN trendline and CWN/PE predictor (black line) in **Figures 3-4 through 3-10**. It generally appears that the greater the disparity between slopes of the Diversion to CWN trendline and the CWN/PE predictor, the stronger the correlation between PE and CWN. The following is a list of months for each SWC member in which this relationship exists:

- A&B – Jul, Aug, Sep, Oct;
- AFRD2 – May, Jul, Sep;
- BID – May, Jun, Aug, Sep, Oct;
- Milner – May, Oct;
- Minidoka – May, Jul, Aug, Sep, Oct;
- NSCC – May, Jun, Jul, Aug, Sep, Oct; and,
- TFCC – May, Jun, Jul, Aug, Sep, Oct.

In my opinion, months with strong PE to CWN correlations reflect months in which there tend to be over-diversions relative to the CWN. In such months, the CWN is easily met and months with greater CWN are months with greater project efficiency.

IDWR's use of fixed monthly project efficiencies for computing RISD from monthly CWN is inconsistent with the relationships in **Figures 3-13** through **3-19** that indicate for many months that project efficiencies vary with CWN. Rather than using the fixed monthly values for project efficiency in Paragraph 32 of the Fifth Methodology Order, the SWC Methodology would be improved in many months by using regression equations based on monthly CWN to compute the monthly project efficiencies that are used in the RISD calculations.

I propose that the regression equations be used in the months of April – September with R-squared values greater than 0.50. In the months in which the regression equation is used, I propose that a floor for the monthly efficiencies be specified based on the average monthly efficiency during 2007 – 2021. This will ensure that the demand calculations use monthly project efficiencies that are at or above average consistent with efficiencies that the historical operational data show they have routinely attained.

In the other May – September months with R-squared values less than 0.50, the regression equation is not a good predictor of the project efficiency. In these months, I propose that the 75th percentile efficiency be used (i.e., the value at which 25% of the monthly project efficiencies are greater). To simplify the procedure, the 75th percentile method could be used in all May – September months.

To avoid use of unreasonably low project efficiencies in October, I propose that the 75th percentile efficiency for September be used for computing the October demand for all SWC members.

The proposed revised procedure for determining the monthly project efficiencies used in computing the monthly diversion demands will result in efficiency values that are at or above the historical averages. This will help avoid unreasonably low efficiency values creating unreasonable shortages to the SWC members requiring undue mitigation or curtailment of junior groundwater users (that generally operate with relatively high irrigation efficiencies).

A hindcast analysis for TFCC and AFRD2 was performed to illustrate the effects of using alternate methods of computing project efficiencies. The project efficiencies were computed using (1) the proposed monthly averages from the Fifth Amended Methodology Order, (2) the regression equations shown on **Figure 3-14** and **Figure 3-19** limited to a minimum of the historical monthly average project efficiency, and (3) the

regression equations on **Figure 3-14** and **Figure 3-19** limited to a minimum of the 75th percentile historical monthly project efficiency. If the regression R-Squared is less than 0.5, the monthly average project efficiency was used for (2), and the 75th percentile historical monthly project efficiency was used for (3). **Table 3-1** and **Table 3-2** show the 2007 – 2021 computed demands (CWN/PE) and the November 1 RISD shortfalls using the three different project efficiency methods for TFCC and AFRD2.

In my opinion, the foregoing discussion clearly and convincingly establishes that the SWC members often operate at unreasonably low project efficiencies, particularly NSCC and TFCC. The proposed procedure will ensure to a clear and convincing standard, that (a) shortages to the SWC members will be computed only when they are operating at reasonable project efficiencies, (b) the SWC members are protected from material injury by junior groundwater pumping, (c) the groundwater users are protected from excessive or undue mitigation obligations and curtailment, and (d) the beneficial uses of the interconnected surface water and groundwater resources of the Snake River and the ESPA are maximized.

4.0 IRRIGATED AREA

The 2008 Order from Hearing Officer Schroeder in the SWC Delivery Call found that non-irrigated acres should not be included in determining the irrigation demands of the SWC members:

> *"Non-irrigated acres should not be considered in determining the irrigation supply necessary for SWC members. IGWA has established that at least 6,600 acres claimed by TFCC in its district are not irrigated. Similar information was submitted concerning the Minidoka Irrigation District, indicating that the claimed acreage of 75,152 includes 5,008 acres not irrigated and Burley Irrigation District has some 2,907 acres of the 47,622 acres claimed not irrigated. These amounts may, of course, change as acreage is removed from irrigation or possibly added back."*
> (IDWR, 2008 at P. 53)

The April As-Applied Order determined that the following acreages for the SWC members will be used to compute the monthly CWN and RISD values using the equations listed above in Section 3.0.

6. Based on the information submitted by the SWC, the Department will use the following total irrigated acres:

	Total Irrigated Acres[1]	Data Source
A&B	15,924	SRBA Partial Decree
AFRD2	62,361	SRBA Partial Decree
BID	46,035	2013 shapefile submitted by BID, reduced by Department for overlapping acres and acres outside of service area.
Milner	13,264	2010 service area shapefile, reduced by Department for overlapping acres and acres outside of service area.
Minidoka	75,093	SRBA Partial Decree
NSCC	154,067	SRBA Partial Decree
TFCC	194,732	2013 shapefile submitted by TFCC, reduced by Department for overlapping acres and acres outside of service area.

As indicated in the above table, the total irrigated area figures for the SWC members are based either on figures from their partial decrees or from shapefiles submitted to IDWR many years ago. Neither of these sources have been shown to reflect the acres actually irrigated by the SWC members.

During the meetings of the SWC TWG held in late 2022, IDWR presented analyses of the SWC member irrigated area in 2011, 2017, and 2021 with non-irrigated acres removed.

The following is a summary of the irrigated area figures that IDWR presented for the three years.

SWC Irrigated Acres

SWC Member	2011 Acres*	2017 Acres*	2021 Acres*	Methodology Acres
A&B	21,585	21,634	21,625	15,924
AFRD2	68,368	66,606	68,384	62,361
Burley	44,113	44,168	44,139	46,035
Milner	13,239	13,202	13,233	13,264
Minidoka	71,295	72,016	71,073	75,093
NSCC	220,953	218,498	220,937	154,067
TFCC	179,486	180,956	179,456	194,732

* with non-irrigated acres removed

According to deposition testimony from Matt Anders, IDWR overlaid aerial imagery from 2011, 2017, and 2021 on the irrigated area shapefiles from the SWC members and determined whether each parcel was irrigated, not irrigated, or partially irrigated. The partially irrigated parcels included hardened acres (roads, buildings, etc.) and other areas that that were not irrigated. If the non-irrigated portions of the partially irrigated parcels were removed, the 2011, 2017, and 2021 irrigated area figures would be lower than the amounts shown in the above table.

The highlighted methodology acres in the above table for Burley, Minidoka, and TFCC represent irrigated acres used in the SWC Methodology that exceed that irrigated acres determined by IDWR. Clearly, based on IDWR's own data, the highlighted methodology acres do not represent the actual irrigated areas of the SWC members. In my opinion, it would be more appropriate to use the 2021 acres for purposes of the demand calculations. The acres in 2021 are shown to be generally consistent with acreages from 2011 and 2017, all of which are less than IDWR's proposed methodology acres.

The 2021 acres for the TFCC are 15,276 acres less than the methodology acres. Based on the weighted average annual crop irrigation requirement for the TFCC over the last 20 years of approximately 2.2 AF/acre and an average project efficiency of 35%, the acreage

difference will overstate the TFCC annual demand by approximately 96,000 AF. This is more than the projected 2023 TFCC shortage of 75,200 AF in the April As-Applied Order.

5.0 SUPPLEMENTAL GROUNDWATER

According to the Fifth Supplemental Order, the use of supplemental groundwater may be considered in determining the irrigated acreage of the SWC members.

> *"In determining the total irrigated acreage, the Department may account for supplemental ground water use. The Department currently does not have sufficient information to accurately determine the contribution of supplemental ground water to lands irrigated with surface water by the SWC. If and when reliable data is available to the Department, the methodology will be amended to account for the supplemental ground water use."*
> (Fifth Methodology Order at P. 40)

IDWR has been asserting a lack of information regarding the use of supplemental groundwater by the SWC members for over ten years. The subject of supplemental groundwater use by the SWC members was raised as a concern in the SWC TWG meetings in 2015 and 2022, and the response has always been that there is not enough information.

In my 2007 expert report for the SWC Delivery Call, I summarized the supplemental groundwater acres based on information the SWC members submitted to the IDWR Director in response to his request for information. The following is the tabulation of supplemental groundwater acres that was in my 2007 report.

Table 3

Supplemental Ground Water Acreage
Surface Water Coalition
(acres)

District/Company	Acres
A&B Irrigation District	-
American Falls Reservoir District #2	11,462
Burley Irrigation District	263
Milner Irrigation District	1,890
Minidoka Irrigation District	4,650
North Side Canal Company	16,358
Twin Falls Canal Company	13,775

Source: Supplemental Response to Director's Information Request, April 15, 2005

IDWR maintains a database and shapefiles for groundwater rights and surface water rights in the state. It would be a relatively simple matter to overlay the shapefiles of the groundwater water right acreages on the shapefiles of the surface water irrigated areas for the SWC members to determine the surface water acres with access to groundwater.

In addition, IDWR now requires all ESPA groundwater pumping to be measured or estimated, so there should be pumping records available for the groundwater rights having acres that overlap the irrigated area shapefiles for the SWC members.

A reasonable mechanism could be developed to estimate the supplemental groundwater use by the SWC members. Repeated assertions that insufficient information is available to assess the use of supplemental groundwater use by the SWC members is unreasonable and is starting to ring hollow.

6.0 TRANSIENT GROUNDWATER MODELING

Until the Fifth Methodology Order, all prior methodology orders determined the priority date for curtailment of junior groundwater users because of a determination of material injury to the SWC members caused by a shortage in RISD or a shortage to reasonable carryover based on steady-state runs of the ESPAM. Repeated ESPAM runs were made simulating the impacts of pumping junior to various assumed priority dates until the annual impact at steady-state to the near Backfoot to Minidoka reach of the Snake River matched the amount of the predicted combined shortage to the SWC members.

The Fifth Methodology Order proposes a sea-change in the procedure for determining the priority date for curtailment of junior groundwater users. Instead of steady-state runs, IDWR will perform transient runs of the ESPAM to determine the priority date of curtailment. IDWR will make repeated transient runs of the ESPAM simulating the impacts of curtailing pumping junior to various assumed priority dates until the impact on the near Blackfoot to Minidoka reach between May 1 and September 30 in the first year of curtailment totals the amount of the predicted combined shortage to the SWC members.

In the April As-Applied Order, IDWR determined curtailment of groundwater rights with priority dates junior to December 30, 1953, was necessary to produce a reach gain to the near Blackfoot to Minidoka reach between May 1, 2023, and September 30, 2023, totaling 75,200 AF (forecast combined shortage to the SWC members in 2023).

IDWR now asserts in the Fifth Methodology Order that it must move from steady-state to transient modeling because it has a better understanding of applying the two different types of modeling and that the calibration using monthly stress periods and halfmonth time steps is a refinement that now allows such a change.

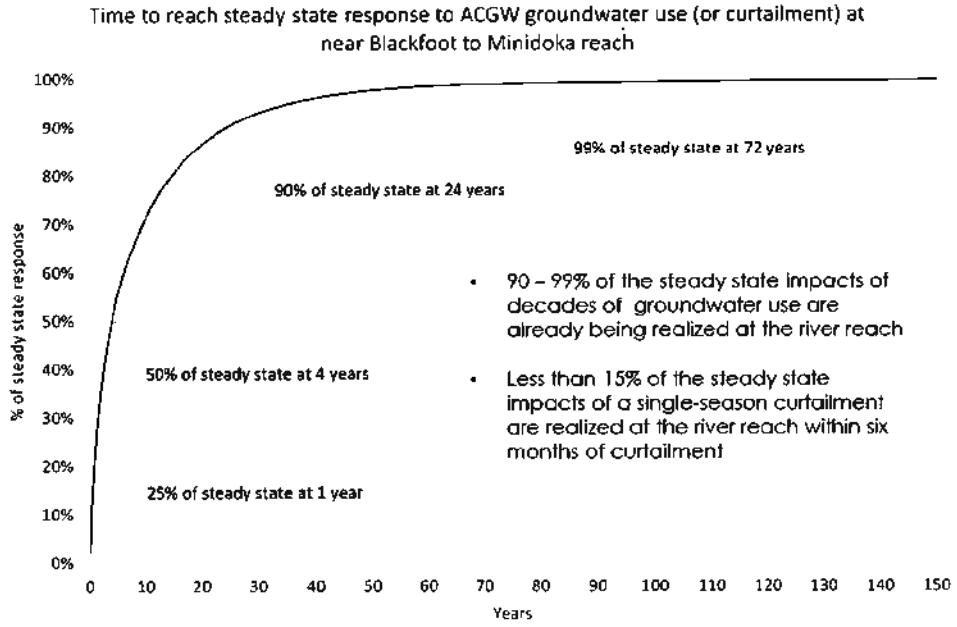
> *"Furthermore, the Department now has multiple years of experience with the methodology to better understand the impact of applying steady-state modeling versus transient modeling to determine a curtailment priority date that would supply adequate water to the senior water right holders. The first version of the ESPA groundwater flow model was not calibrated at a time-scale that supported in-season transient modeling. In contrast, the current version was calibrated using monthly stress periods and halfmonth time steps, a refinement that facilitates in-season transient modeling for calculating the response to curtailment of groundwater use. The purpose of this Fifth Amended Final Order Regarding Methodology for Determining Material Injury to Reasonable In-Season Demand and Reasonable Carryover ("Fifth Methodology Order") is to update the Director's methodology for determining material injury to storage and natural flow water*

rights either held by or committed to members of the SWC consistent with the Director's ongoing obligation to use the best available science and information." (Fifth Methodology Order at P.2)".

IDWR asserts in the Fifth Methodology Order that curtailment of groundwater rights junior to a curtailment date determined based on steady-state modeling would not produce sufficient water during the first year of curtailment to offset the impact to the senior surface water rights.

"Only 9% to 15% of the steady state response is predicted to accrue to the near Blackfoot to Minidoka reach between May 1 and September 30 of the same year. Fifty percent of the steady-state response is predicted to accrue at the near Blackfoot to Minidoka reach within approximately four years. Ninety percent of the steady-state response is predicted to accrue at the near Blackfoot to Minidoka reach within approximately 24 years." (Fifth Methodology Order at P. 30).

The Fifth Methodology Order cites the mechanism used for surface water administration in support of the need for transient curtailment analysis.



"In surface water administration, uses by holders of junior priority surface water rights are curtailed until the senior surface water rights are fully satisfied, absent a futile call and if the senior surface water users need the water to accomplish a beneficial use. In other words, under surface water administration, junior surface water rights are generally curtailed unless the senior gets water in the quantity and at the time and place required." (Fifth Methodology Order at P. 35).

Monthly stress periods and halfmonth time steps have been part of the ESPAM model since 2013 and are not new refinements. Prior to ESPAM 2.1, the differences between steady-state modeling and transient modeling were well understood by IDWR and the ESHMC members and were frequently discussed during meetings.

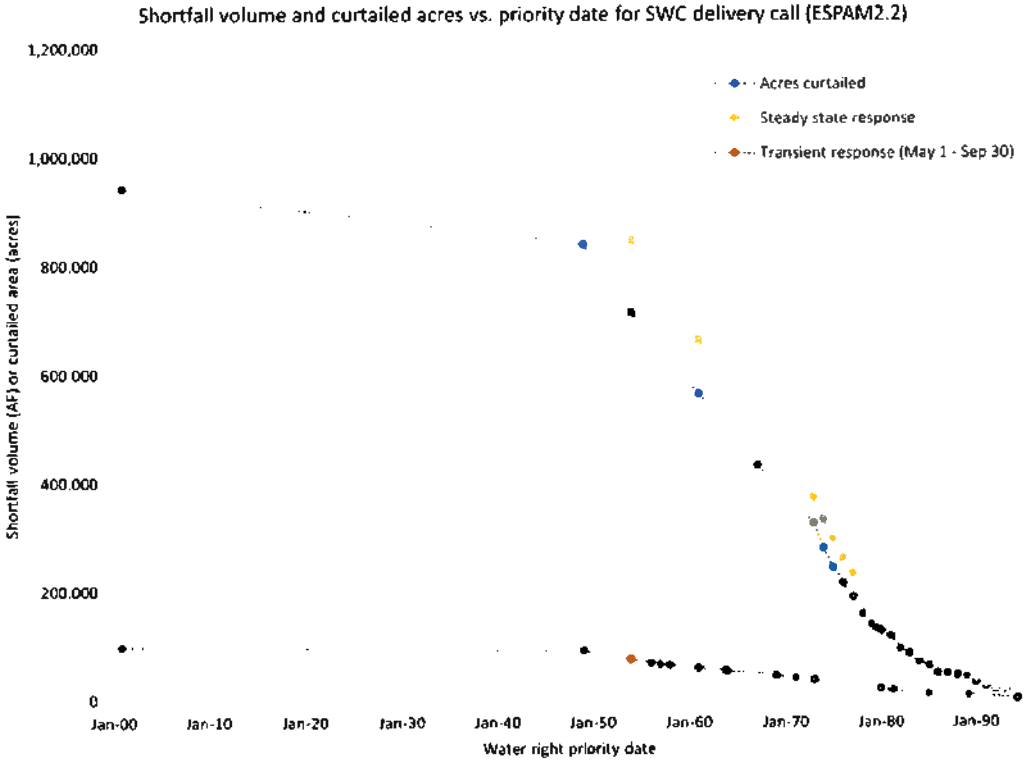
In my opinion, given the circumstances of the conjunctive administration of groundwater and surface water in the Upper Snake River Basin, use of steady-state modeling to determine the priority date of curtailment is reasonable and appropriate. In addition, as described below, administration that treats ground water rights like surface water rights (i.e., by requiring curtailment to satisfy seniors) is grossly inefficient and results in disproportionate impacts on junior ground water users.

There has been a moratorium against new groundwater development in the ESPA without mitigation since 1993. Therefore, all pre-moratorium wells have been pumping for at least 30 years, and most wells for much longer. As a result, the effects of the pumping by pre-moratorium wells on Snake River flows have reached near steady state. This is

evident in the following results of a curtailment run that was presented by Jennifer Sukow (IDWR) during the November 28, 2022, TWG meeting (Slide 6) that show the effects of ESPA pumping are approximately 93% of steady-state after 30 years and 98% of steady-state after 50 years:

It follows that the steady-state curtailment runs that IDWR has used for eighteen years, since the Director issued his first SWC curtailment order in 2005, represent reasonable estimates of the last increment of depletions to the near Blackfoot to Minidoka reach being caused by wells that are junior to the simulated curtailment date. These impacts reflect the aggregated impacts of all current and prior pumping by the junior wells. In my opinion, steady-state modeling is the technically correct way to determine the curtailment date for the SWC Methodology.

In Colorado, it was recognized early on that it was impractical to conjunctively administer wells and surface water rights in the same manner as administration between surface water rights because of the delayed impacts on surface streams from curtailing groundwater pumping. Use of transient modeling effectively attempts to administer groundwater rights as if they were surface water rights, which is ill advised because of the delayed response of streamflows to groundwater curtailment. A more elegant and efficient solution is to require junior groundwater users to offset impacts to senior surface water rights caused by current and prior pumping. In that way, the seniors are protected



from injury and the junior groundwater users can continue to pump. This was the practice in Idaho until the imposition of the Fifth Methodology Order and has been the practice in Colorado for over 50 years.

In Colorado, junior groundwater users are required to have a judicially or administratively approved plan in place that is capable of replacing the injurious impacts on surface users in time, place, and amount in order for the juniors to pump any groundwater. Otherwise, the junior groundwater user is permanently curtailed unless or until they can obtain approval of a replacement plan.

In sum, the process of determining curtailment dates based on steady-state runs should *continue* to be applied in the Upper Snake River Basin because it will properly assign the obligation for mitigating any computed shortages to the SWC members to the junior groundwater users whose current and prior pumping is the cause of the shortage.

Further, in my opinion, implementation of transient groundwater modeling in the Fifth Methodology Order will cause injury to certain groundwater users by requiring them to mitigate for impacts to senior surface water rights that they did not cause.

Consider the present situation with a predicted shortage to the TFCC of 75,200 AF in 2023. It is the last 75,200 AF of depletions to the near Blackfoot to Minidoka reach that created the current shortage. Based on the following graph presented by Jennifer Sukow during the November 28, 2022, TWG meeting, curtailment of pumping from wells junior to sometime in the mid-1980s would produce 75,200 AF/y of water at steady state to the near Blackfoot to Minidoka reach.

In other words, the last 75,200 AF of depletions to this reach that created the shortage to the TFCC was caused by wells junior to the mid-1980s.

Under the prior appropriation doctrine, the wells senior to the mid-1980s are entitled to the conditions that existed at the time of their appropriation. Among those conditions would be that the last 75,200 AF of depletion to the near Blackfoot to Minidoka reach caused by more junior wells would not have occurred and would not have created the shortage to TFCC that exists in 2023. Curtailing or requiring mitigation from groundwater rights in 2023 with priority dates senior to the mid-1980s would injure those groundwater rights because pumping under these more senior groundwater rights did not create the shortage to the TFCC this year. The obligation to mitigate the 75,200 AF of shortage to the TFCC in 2023 should be shouldered by wells junior to the mid-1980s. These are the wells whose current and prior pumping created the shortage in 2023.

7.0 SUMMARY OF OPINIONS

Based on my review and analysis of the materials disclosed by IDWR, my involvement in SWC Delivery Call matters since 2005, and my 37 years of experience in conjunctive administration of groundwater and surface water rights, the following is summary of my professional opinions on the Fifth Methodology Order and the April As-Applied Order.

1. IDWR made substantive changes to the SWC Methodology in the Fifth Methodology Order including a change in the BLY used to forecast SWC member demands at the beginning of the year, changes in the monthly project efficiencies used to compute demands mid-season, and changes in how the priority date for curtailment of junior groundwater users is determined.
2. It has been over 15 years since the last comprehensive review of the SWC Methodology. During that time, there have been numerous changed conditions that dictate that all elements of the SWC Methodology be reassessed to determine if they remain appropriate for determining shortages to the SWC members caused by junior groundwater pumping and whether the proposed changes to the SWC Methodology are reasonable and appropriate.
3. The proposed change in the BLY from 06/08/12 to 2018 that increased the combined BLY demand by approximately 142,000 AF was arbitrary and unreasonable given that the 06/08/12 BLY is only 40 AF (0.001%) less than the 2000 – 2021 average diversions. Further, if the diversions from 2022 are considered in computing the average annual diversions, then the 06/08/12 diversions would still be above average and would still qualify as a BLY.
4. The combined diversions of the SWC members have increased by an average of 148,826 AF since 2005 while average project efficiencies of most SWC members have declined. IDWR has not analyzed the reasonableness of these changes in light of the substantive increases these changes will cause to the computed shortages of the SWC members.
5. Continued sprinkler conversions and advancements in irrigation technology and management suggest that project efficiencies should have increased over the last 15 years rather than decreased.
6. Lower project efficiencies for certain of the SWC members in some or all months will cause unreasonable increases in computed diversion demands and water shortages, especially for TFCC.

7. Unreasonably low efficiencies during the shoulder months of April, May, September, and October will cause unreasonable monthly water demands, especially in months when the CWN is greater than average.

8. Industry standard procedures should be employed to assess the reasonableness of the monthly project efficiencies of the SWC members, including the reductions in project efficiencies that have occurred over the last 15 years. IDWR employed such procedures in evaluating whether Unit B was short of water in assessing the A&B delivery call in 2008.

9. Scatter plots of monthly diversions vs CWN during the last 15 years show that CWN is often a poor predictor of the diversion demands of the SWC members. This indicates that the SWC Methodology should be examined and revised to improve how the diversion demands of the SWC members are determined.

10. Project efficiencies are unexpectedly well-correlated to CWN for many SWC members in some months and for NSCC and TFCC in most months. This is a symptom of more water being diverted than is needed to meet crop water demand.

11. Use of CWN and average monthly project efficiencies will overstate SWC diversion demands in months with above average CWN.

12. The SWC Methodology would be improved by changing the way that monthly project efficiencies are determined for computing RISD. Regression equations based on CWN should be used for months with a moderate to strong correlation (R-squared > 0.5) with a floor no lower than the average monthly efficiency during the past 15 years. In months without a good correlation to CWN (R-squared < 0.5), project efficiencies should be set at the 75th percentile of efficiencies during the past 15 years. The monthly efficiency values for September should be used for October.

13. The irrigated area determined from shapefiles submitted by several of the SWC members exceeds the irrigated area determined by IDWR from analysis of aerial imagery and remote sensing in recent years. It is unreasonable and unlawful for non-irrigated acreages to be included in computing the CWN of the SWC members.

14. The discrepancy between claimed and actual irrigated area is especially egregious for TFCC which claims an irrigated area that is 15,276 acres greater than the irrigated area determined by IDWR in 2021. Based on an average annual ET rate of 2.2 AF/ac and an average project efficiency of 35%, the acreage discrepancy for TFCC would amount to approximately 96,000 AF, which is greater than the forecast shortage for TFCC in 2023 of 75,200 AF in the 2023 April As-Applied Order.

15. The SWC Methodology has long specified that supplemental groundwater pumping be considered in determining whether shortages to the SWC members exist. However, IDWR has done nothing over the past fifteen years to quantify or estimate the supplemental pumping of the SWC members. This is despite the availability of groundwater right mapping and groundwater pumping records that could be analyzed to reasonably determine the supplemental pumping of the SWC members.

16. The change in use of the ESPAM to determine the priority date of curtailment based on transient groundwater modeling is unreasonable because it will result in groundwater users having to mitigate or be curtailed for shortages to the SWC members that they did not cause. This is counter to the prior appropriation system and will cause injury to groundwater users.

17. Steady-state groundwater modeling is more appropriate for use in determining the priority date of curtailment for purposes of the SWC Methodology because virtually all of the ESPA pumping has been occurring since at least the early 1990s when the moratorium against new wells was instituted, and by 2023, the effects of ESPA pumping on Snake River flows have reached near-steady state.

18. Use of transient groundwater modeling to determine the priority date of curtailment improperly attempts to conjunctively administer groundwater rights under surface water right administration procedures. Conjunctive administration through curtailment is extremely inefficient and counter to mechanisms developed in Colorado and other western states in which conjunctive administration is enacted through replacement of depletions rather than through curtailment.

8.0 INFORMATION RELIED ON

The following information was relied upon in preparing this expert report.

Anders, Matthew. 2023. Deposition of Matthew Anders, P.G. on May 12, 2023. In the Matter of the Request of Administration in Water District 120 and the Request for Delivery of Water to Senior Surface Water Rights by A&B Irrigation District, American Falls Reservoir District #2, Burley Irrigation District, Milner Irrigation District, Minidoka Irrigation District, North Side Canal Company, and Twin Falls Canal Company ["SWC"]. Including documents produced at deposition.

Exclude PE Outlier Months (> +/- 2 Std Dev)

Notes:

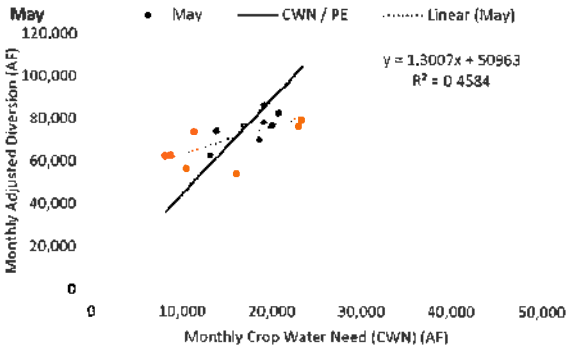
(1) Monthly Crop Water Need (CWN) is the crop weighted average irrigation water requirement multiplied by the District reported irrigated area. (IDWR Spreadsheet: "DS RISD Calculator_2022_06-08-12_update to 15 yr avg_ used for order.xlsx").



(2) Monthly Adjusted Diversion are historical reported diversions adjusted for wheeled water and recharge (IDWR Spreadsheet: "DS RISD Calculator_2022_06-08-12_update to 15 yr avg_used for order.xlsx").

(3) Monthly PE (colored dots) computed as the monthly CWN (1) divided by monthly Adjusted Diversion (2).

Summary of Water Rights
City of Pocatello

	Water Right	Water Rights							(1) Historical Well No. or Source	AKA/Name	Aquifer
		Priority Date	Diversion Rate (cfs)	Cum Rate (cfs)	Vol Limit (af/y)	Irrigated Acreage	Season of Use	Purpose of Use			
	OTHER WATER RIGHTS										
(7)	29-2354	8/27/1954	0.28	0.28	56.0	19.0	4/1 - 10/31	Irrigation	Restlawn Cemetery		LPRVA
	29-2382	12/21/1956	3.82	4.10	450.0	-	4/1 - 10/31	Municipal	17	Highland GC	LPRVA
	29-13636	10/16/1958	0.80	4.90	-	-	1/1 - 12/31	Municipal	19		ESPA
	29-7222	8/22/1974	1.00	5.90	-	50.0	4/1 - 11/1	Irrigation	43	Ward Park	ESPA
	29-7431	12/29/1977	9.28	15.18	3,108.0	777.0	4/1 - 11/1	Irrigation	Wastewater		N/A
(7)	29-7502	7/6/1979	0.10	15.28	20.0	19.0	3/15 - 11/15	Irrigation	Restlawn Cemetery		LPRVA
	STORAGE RIGHTS										
	01-2068	7/28/1939	50,000 AF	-	50,000 AF	-	1/1 - 12/31	Storage	Palisades Reservoir		N/A

Notes:

(1) Flow rate in parenthesis is the diversion rate associated with individual well to the extent necessary for administration between points of diversion for ground water, and between points of diversion for ground water and hydraulically connected surface sources.

(2) "IC Wells" - Municipal water rights decreed in SRBA with 22 PODs for ground water rights.

(3) "IC Wells" - Municipal water rights decreed in SRBA with 13 PODs for ground water rights. Water right part of Transfer No. 5452.

(4) Post SRBA water right.

(5) "IA Wells" - Municipal water rights decreed in SRBA with 2 PODs for ground water rights.

(6) Use of water right nos. 29-2255D and 29-2255F is limited to the irrigation of a combined total of 44.1 acres in a single irrigation season.

(7) Use of water right nos. 29-2354 and 29-7502 is limited to the irrigation of a combined total of 19.0 acres in a single irrigation season.

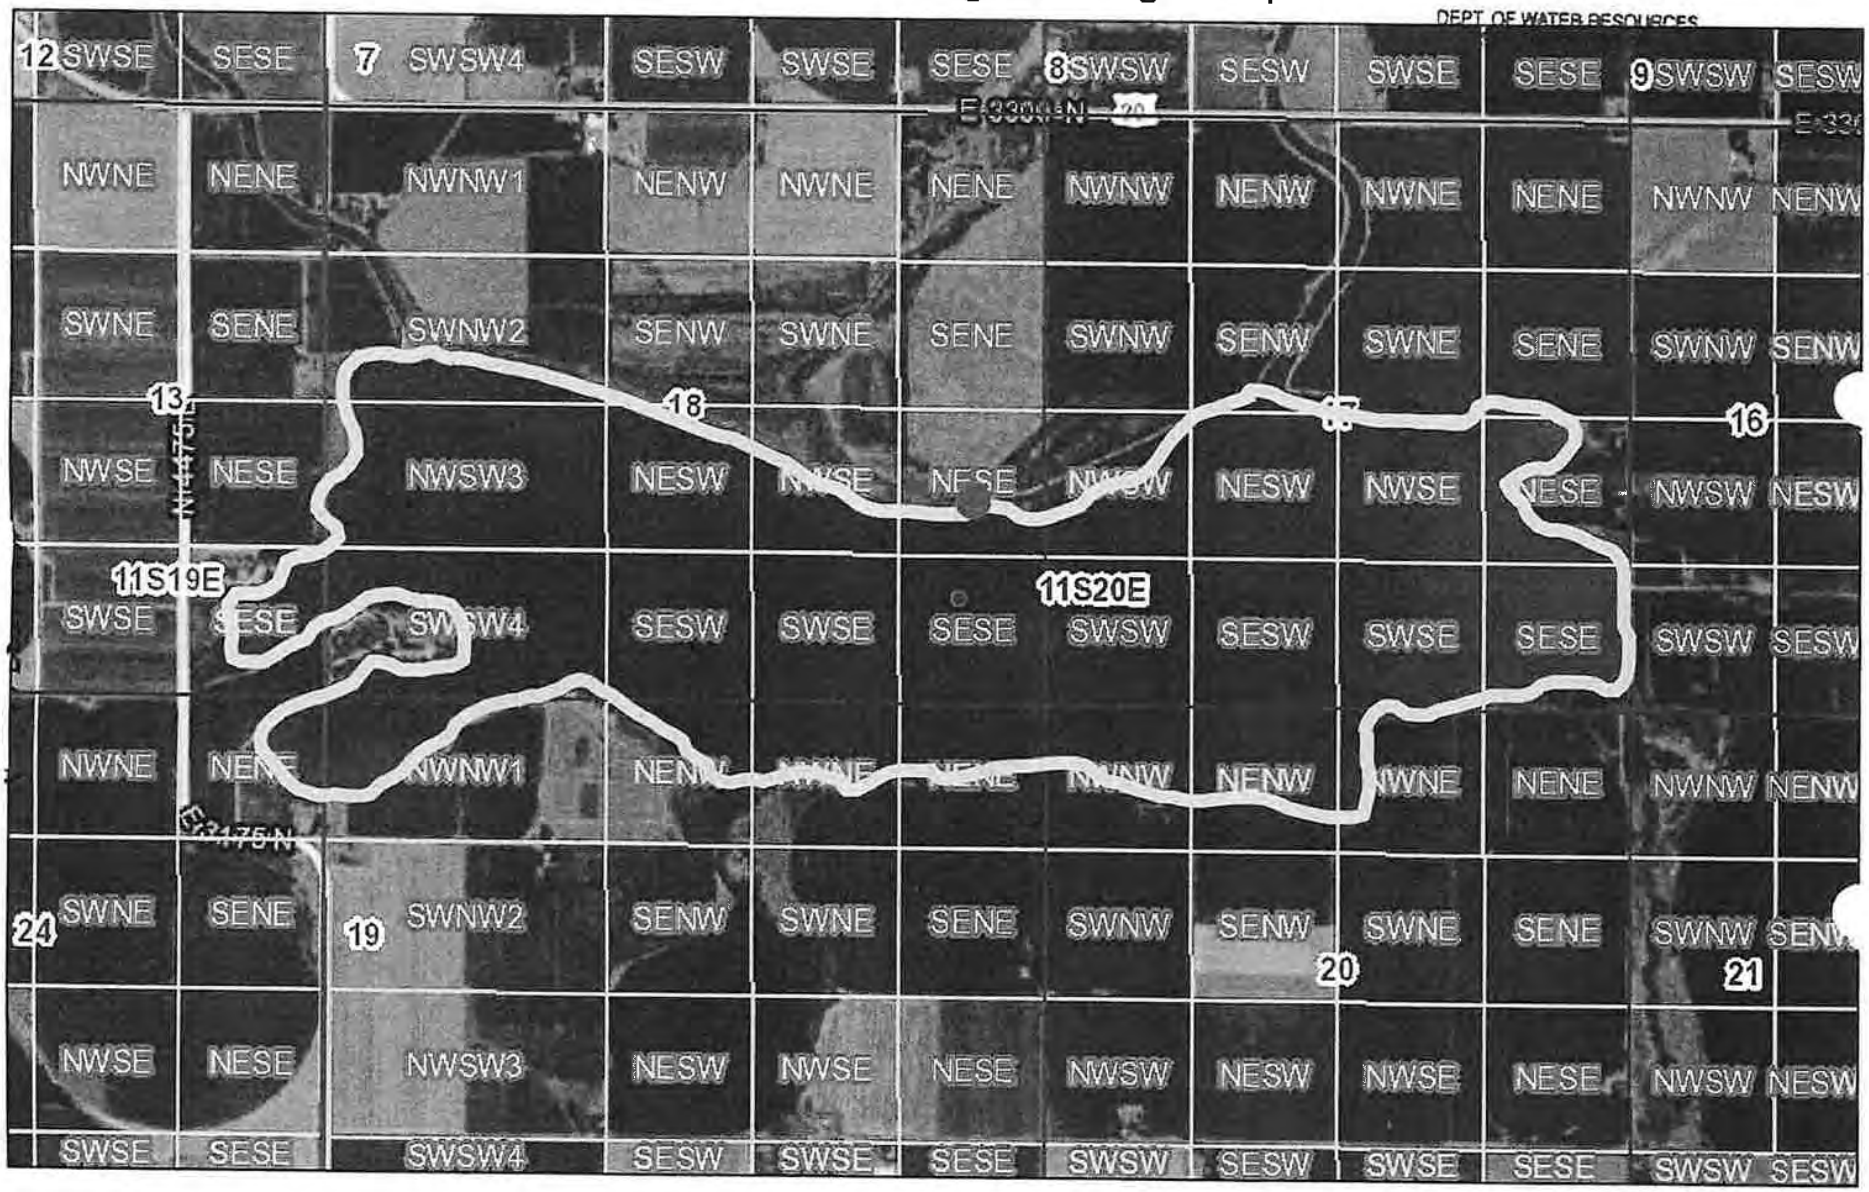
Amended



10. Supplemental Information: Southwest Irrigation District holds water rights for recharge from Dry Creek. The water right in this application would be junior to those existing water rights for recharge.

11a & c. Supplemental Information: The land at the point of diversion and place of use, Murtaugh Lake, is owned by the State of Idaho and the United States. Murtaugh Lake, its dam and associated irrigation facilities, are owned and operated by Twin Falls Canal Company as part of Carey Act filing of 1900 that allowed for the construction of these facilities.

12. Supplemental Information: Twin Falls Canal Company is applying for a water right for the ground water recharge that occurs through seepage from Murtaugh Lake when water from Dry Creek, a tributary to Murtaugh Lake, discharges into the lake. Dry Creek is dry throughout much of the year, but when it discharges water into Murtaugh Lake, the Main Line Canal is shutoff so that the lake is filled with water from Dry Creek.

CONTRACT

Between State Board of Land Commissioners and Twin Falls Land & Water Company

Dated January 2, 1903

THIS AGREEMENT, made and entered into in duplicate this 2nd day of January, 1903, by and between the State of Idaho, the party of the first part, through the State Board of Land Commissioners of said State, said Board consisting of Frank W. Hunt, Governor, C. J. Bassett, Secretary of State, Frank Martin, Attorney General, and Permeal French, Superintendent of Public Instruction of said State, and the Twin Falls Land and Water Company, a corporation organized and existing under the laws of the State of Utah, the party of the second part, Witnesseth:

That, Whereas the party of the second part did heretofore, to-wit: on the 12th day of October, 1900, file with the State Board of Land Commissioners of the State of Idaho, a proposal for the construction of certain irrigation works in the counties of Cassia and Lincoln in the State of Idaho, under the provisions of the Act of Congress commonly known as the "Carey Act," and the acts amendatory thereof and the laws of the State of Idaho enacted in pursuance of the power granted by the said Act, and, whereas, at the request of the State of Idaho the lands lying under said irrigation works have been by contract between the United States and the State of Idaho, dated July 1st, 1901, set apart by the United States in compliance with the provisions of said Acts of Congress, said lands being List Numbered Six of the State of Idaho, filed at the United States Land Office at Hailey, Idaho, and more fully described in the contract above mentioned between the United States and the State of Idaho; and, whereas said State Board of Land Commissioners have duly notified the said party of the second part to enter into a formal contract for the construction of said irrigation works in pursuance of said proposal; said irrigation works being known as the Twin Falls Dam and Canals, and whereas said State Board of Land Commissioners did on the 2nd day of January, 1903, resolve to enter into a contract with the said pary of the second part for the construction of said irrigation works, it is therefore mutually covenanted and agreed as follows:

PURPOSE OF CONTRACT

First: That for and in consideration of the covenants of said party of the first part herein contained, the party of the second part agrees to construct and build the said Twin Falls Dam and Canals and their main laterals, beginning at the points of diversion particularly described and designated on the map descriptive of said canals and the lands herein described, which map is hereto attached and made a part of this contract, marked Exhibit A, a copy of which is filed in the office of the State Engineer, and to sell shares or water rights in said canal system from time to time as hereinafter provided, to the persons filing upon the lands hereafter described, and to the owners of other lands not described herein but which are susceptible of irrigation from this canal system said shares or water rights to be sold on the terms herein provided, and to transfer the ownership, management and control of said system to said purchasers of shares or water rights as hereinafter provided.

GENERAL SPECIFICATIONS FOR CONSTRUCTION

Second: It is hereby agreed that the party of the second part shall construct the said Dam and Canals and Lateral system according to the following specifications:

The proposed point of diversion of the south side canal is situated north 30 degrees west 1320 feet from the southeast corner of Section 29, Township 10 South, Range 21 East. The point of diversion of the north side canal is situated south 2 degrees 20 minutes west 2425 feet from the northeast corner of Section 29, Township 10 South, Range 21 East.

General description of proposed works is as follows:

Dam: Water to be raised above its present level thirty-eight feet by closing the present three channels of the river by loose rock embankment or masonry or concrete dams, thereby forcing the water over two islands of solid lava rock, which will be blasted down to form a suitable crest and will give a free waterway of 815 feet. Rock embankment to be carried six feet above extreme high water, to have a slope of 1:1 and to be backfilled with gravel or earth on slope of 1 1-2:1.

South side canal: Total length about sixty-five miles. First section (from point of diversion to Rock Creek) eighty feet on the bottom, gradually narrowing to sixty feet on the bottom at Rock Creek. Slope of sides 2:1 depth of water ten feet, lower bank twelve feet on top; grade one foot to 5000 feet, capacity three thousand second feet. From Rock Creek to terminus bottom width gradually narrowed from sixty feet to fifteen feet, slopes 1 1-2:1, grades increased to two feet to 5000 feet at lower end. Rock Creek at head extends for one and one-half miles estimated sixty per cent solid rock, balance of canal in earth until last twenty miles, where it is estimated fifty per cent of loose rock will be encountered.

North side canal: Total length about twenty miles. First section (being the first thirteen miles of the canal) twenty-five feet wide on the bottom, gradually narrowing to twenty feet at the end of the thirteenth mile. Second section from end of thirteenth mile to terminus, gradually narrowing to ten feet in width at terminus. Slope of sides, 1 1-2:1, depth of water 5 1-2 feet; grade 1 foot to 2640 feet; capacity 400 second feet. The first mile will be in heavy rock cuts, balance of canal in earth.

Structure: Both headgates will be built in solid rock. The main waste gates or spill ways will be located near the head of the canal in solid rock. All other waste gates, lateral gates and weirs will be of masonry or concrete.

Laterals: Approximately one hundred and twenty miles of main and three hundred and eighty miles of subordinate laterals are required with the necessary weirs and distributing gates. In case of variance between these specifications and Exhibit A, these specifications shall control.

Said dams, canals, laterals, gates, weirs and all other structures to be built and constructed in a workmanlike manner.

It shall be the duty of the said second party to file with the State Engineer of Idaho notes showing the size and the courses and distances from angle to angle of the canals and main laterals as soon as the same shall have been finally determined.

Changes may be made in these specifications from time to time by agreement between the State Engineer and said second party; such changes, however, not to impair the efficiency of the works for the purposes for which they are intended.

Said second party shall on demand of first party, furnish any further detailed specifications that may be required.

The main canals of this system shall have a carrying capacity when completed sufficient to deliver simultaneously one second foot of water to every eighty acres of land described in this contract, together with all other lands susceptible of irrigation from said canals as nearly as the same can be estimated and agreed upon between the State Engineer and the Engineers of the second party.

The plans, specifications and details for the construction of the dam, canals, headgates, weirs, etc., so far as the same are not covered by the above specifications, shall be submitted to the State Engineer of Idaho for his approval prior to the construction of any of said works, with the right of appeal by said second party from his decision to the State Board of Land Commissioners; but the work, when completed, shall be in accordance with the specifications as finally determined upon to the satisfaction of the State Engineer.

RIGHTS OF WAY

Third: The said party of the first part hereby grants to the said party of the second part a right of way across lands belonging to the State of Idaho or that may be ceded to the State, for the construction and operation of said canals and main laterals, which right of way shall be equal to the actual width of said canals or laterals at their base from toe to toe of the embankment of the same together with a strip of land along one side of each canal or lateral, and adjacent thereto; said strip of land not to exceed fifty (50) feet in width along the main canal, thirty (30) feet in width along main laterals, and a proportionate width along smaller laterals.

APPROPRIATION OF WATER

Fourth: As there has been issued by the State Engineer to the party of the second part a permit to construct said irrigation works and to divert and appropriate from the waters of Snake River 3400 second feet for the purpose of irrigation, power and other beneficial uses, said permit being dated October 8th, 1900, the said party of the second part agrees to cause to be furnished and delivered to said canals all of said appropriated waters to irrigate and reclaim such portions of the following described lands together with such portions of other lands not described herein, but which lie below the line of said canal as are susceptible of irrigation and reclamation therefrom, and said second party hereby covenants and agrees that it has not done, suffered or permitted any act or thing by reason whereof the appropriation so made by it as aforesaid of the said waters of Snake River for the purposes of the irrigation and reclamation of lands through the system of works to be constructed hereunder has been or in future may be in any way impeached, clouded or impaired.

ENTRY OF LANDS

Fifth: Upon the execution of this contract and when the actual construction of said canal shall have been inaugurated, and so far completed as to insure that said water will be furnished the hereinafter described lands, the State Board of Land Commissioners shall cause to be opened for settlement as provided by law, the following described portion or parcels of the land herein described, to-wit:

All of that portion of said lands on the southerly side of Snake River under said canal system that is shown on the map Exhibit A herewith, lying to the east and south of the east line of section sixteen (16), township nine (9) south, range nineteen (19) east, Boise Meridian.

Also all of the said lands on the northerly side the Snake River under said canal system as shown on said map, Exhibit A.

That when said canal on the southerly side of Snake River shall have been completed to a point twenty (20) miles measured along its course from the dam and head of said canal, then the State Board of Land Commissioners shall cause to be opened for settlement in like manner the following described lands, to-wit:

All of said lands under said canal lying to the east of the west boundary of township ten (10) and eleven (11) south of

45-14537 (4 pgs)

range seventeen (17) east of Boise Meridian as shown on the map, Exhibit A.

And when said canal on the southerly side of Snake River shall have been completed to a point thirty (30) miles measured along the canal from the head thereof, then the remaining portion or parcels of said land shall be thrown open for settlement in the manner provided by law.

APPLICATION FOR LANDS

Sixth: The said party of the first part through its State Board of Land Commissioners, agrees that it will not approve any application for or filing on said lands until the person or persons so applying shall furnish to the said Board a true copy of the contract entered into with the said party of the second part for the purchase of sufficient shares or water rights in said irrigation works or shares of stock in the corporation owning, controlling and managing the same for the irrigation of the lands applied for. The second party stipulates and agrees that to the extent of the capacity of the irrigation works, and as rapidly as lands are opened for entry and settlement, it will be filed upon to qualified entrymen or purchasers, without preference or partiality other than that based upon priority of application.

SALE OF LAND BY THE STATE

Seventh: That the said party of the first part, acting through its State Board of Land Commissioners, agrees to sell the lands herein described to such persons as are or will be, by law entitled to file upon the same, for the sum of Fifty (50c) Cents per acre, one-half of which shall be paid at the time of application for the entry of such lands made to said Board and the remaining one-half at the time of making final proof on the land as required by law.

PRICE OF WATER RIGHTS

Eighth: Said party of the second part further agrees and undertakes that it will sell or cause to be sold to the person or persons filing upon any of the lands herein described or to the owner of other lands not described herein, but susceptible of irrigation from its said canal system, by good and sufficient contract of sale with right of possession and enjoyment by the purchaser pending its fulfillment, a water right or share in the said canal for each and every acre owned, filed upon or purchased from the State.

Each of said shares or water rights shall represent a carrying capacity in said canal sufficient to deliver water at the rate of one-eightieth of one second foot per acre, and each share or water right sold or contracted as herein provided shall also represent a proportionate interest in the said canal together with all rights and franchises based upon the number of shares finally sold in the said canals.

Such water rights or shares shall be sold to the person or persons aforesaid as follows: To the person or persons filing upon any of the lands herein described at a price not exceeding $25.00 per share, the same to be paid for as follows: One-fifth in cash at the time of sale and the remainder in five annual installments bearing interest at the rate of six per cent per annum; to the person or persons purchasing any portion of sections numbered sixteen or thirty-six, or any other lands belonging to the State of Idaho which are susceptible of irrigation and reclamation from this canal and to which such water rights are to be applied and dedicated at a price not exceeding fifteen and 50-100 ($15.50) dollars per share provided said water rights are purchased within one year after date of sale or contract by the State of Idaho, and not exceeding Twenty-five ($25.00) dollars at any time thereafter; and to the person or persons owning other lands not herein described but susceptible of irrigation and reclamation from this canal, and to which said water rights or shares are to be applied or dedicated at a price not exceeding Twenty-five ($25.00) dollars per share, payment in either case to be made therefor in installments upon interest as hereinbefore provided in the case of other lands.

This agreemtn shall not, however, be construed to prevent the sale of shares or water rights to purchasers on terms more favorable than those hereinbefore provided, or to prevent payment of installments or purchase price in advance of the maturity of the same at the option of purchaser.

But in no case will water rights or shares be dedicated to any of the lands aforementioned or said beyond the carrying capacity of the canal system, nor in excess of the appropriation of water as hereinbefore mentioned.

It is expressly agreed that prior to the time when the said water rights or shares shall have been converted into or replaced by shares of stock of the Twin Falls Canal Company, Limited, a corporation to be formed as hereinafter provided, said water rights or shares in this section referred to shall be understood to represent only a right to the use and enjoyment of the water flowing through or supplied by the canal system, and shall not in any case be held or understood to transfer to or vest in the purchaser thereof a right of ownership in the dam, or rights of way, canals, headgates, weirs or other irrigation works, or the right to interfere or participate in the control or management thereof as against the said second party.

It is further stipulated and agreed that any and all contracts upon which water rights or shares in the canal are sold, may by express agreement, provide that upon full payment of the purchase price there shall be given at the option of the second party hereto either a warranty deed for an undivided interest in the canal system or shares in the Twin Falls Canal Company, Limited, hereafter described, one share of stock for one share of water right.

Whereas, it is determined to be necessary to provide a convenient method of transferring the ownership and control of said canal from the purchasers of shares or water rights in said canals, and determining their rights among themselves and between said purchasers and the party of the second part herein, and for the purpose of levying and collecting reasonable tolls, charges and assessments for the care and maintenance of said canals, it is hereby further provided that at any time after the completion of the entire system of dam and canals as hereinbefore provided in the specifications and within seven (7) years from the date of this contract, or at any time prior thereto, upon the consent of the State Board of Land Commissioners, a corporation shall be formed under the laws of the State of Idaho, to be known and called the Twin Falls Canal Company, Limited, having the powers and limitations and with the mutual covenants and agreements substantially as set forth in the draft of the Articles of Incorporation hereunto attached marked Exhibit B. "But said Articles of Incorporation must conform to the provisions of this contract, and must be approved by the State Board of Land Commissioners before said corporation can be formed." The said corporation shall be formed by said second party at its expense, all the stock thereof being subscribed by the second party and such other persons, not exceeding six, as may be necessary and all the stock being subscribed by or for said second party. And immediately upon the formation of said corporation said second party shall by good and sufficient deed convey to it the dam and entire system of canals, and the dam and irrigation works and the water rights connected therewith, free of all debt, lien or encumbrance. And upon the formation of said corporation, the shares or water rights theretofore sold or contracted to be sold shall be converted into or replaced by the shares of said corporation, share for share, and from and after the date of the formation of said corporation the party of the second part shall sell to purchasers or owners of lands under the canal system shares of stock of said corporation upon the same terms in all respects as hereinbefore provided for the sale of water rights or shares prior to the formation of such corporation. The said second party agrees that until it shall have assigned and transferred to settlers and owners of lands under said canal a majority of the stock of the Twin Falls Canal Company, Limited, and thereafter so long as it shall manage and control the said canal system there shall be delivered through the canals and laterals the water flowing therein equally and proportionately according to the representative rights of the parties entitled thereto.

Any and all deferred payments for the purchase price of water rights or shares of stock may be secured by express contract of the purchaser pledging the water right or stock sold together with any and all rights in the lands to which the water is to be applied and the lien thereby granted shall be in addition to all liens granted by the laws of Idaho.

WATER RIGHT DEDICATED

Ninth: The certificates of sale of water rights and the certificates of shares of stock of the Twin Falls Canal Company, Limited, shall each upon being issued to the purchaser or holder of land under the canal system, be made to indicate and define in the contract or certificate as the case may be, the amount of water, to-wit: One eightieth of a second foot allotted to each acre represented thereby, and carrying capacity of the canal sufficient therefor, the water to be delivered from the canal during each and every irrigation season, said amount to be measured at or within one-half mile of the place of intended use in such quantities and at such times as the condition of the soil, crops and weather may determine but according to such rules and regulations based upon a system of distribution of water to the irrigators in turn and by rotation as will best protect and serve the interests of all the users of water from this canal system. It is agreed that said system of distribution by rotation shall be devised by the said party of the second part and used by it during the period while it retains the management of said system, and that it shall meet the approval of the State Engineer.

The sale or contract of the water right to the purchaser shall be a dedication of the water to the land to which the same is to be applied, and the water right so dedicated shall be a part of and shall relate to the water right belonging to the said system of canals.

All deeds for water rights if any be issued by the said second party, shall be based upon this contract, and shall meet the approval of the said party of the first part, the State of Idaho.

MEASUREMENT OF WATER CHARGES FOR DELIVERY

Tenth: The said party of the second part agrees to construct and until it shall convey and turn over the title and possession to the Twin Falls Canal Company, Limited, to operate said canal and main laterals so that water conducted through the same may be delivered at a point not exceeding one-half mile from any legal subdivision of one hundred and sixty acres of land herein described, filed upon, owned or occupied as aforesaid and to be irrigated or reclaimed by the water conducted through said canals and main laterals. That it will construct and place in position and while it retains possession, maintain all headgates, flumes, weirs and other devices through which water may be turned off from said canal or main laterals; that the said party of the second part will construct and place in said canal or laterals such devices for measuring water to irrigators as shall be deemed necessary and best by the State Engineer of Idaho.

It is hereby agreed that every purchaser of shares in said canal or holder of stock in said Twin Falls Canal Company, Limited, shall be entitled to have delivered for the irrigation of his land, its full amount of water as herein provided, and it is hereby stipulated and agreed that while it retains pos-

001886

session and control of said canal system the party of the second part may make a charge for the delivery of said water for irrigation to the purchaser of said shares on the following basis and in the following manner: All of the water dedicated to his land shall be delivered free of all charges during the first irrigating season that water is delivered to said purchaser, and thereafter an annual charge not to exceed 60 cents per acre may be made for each and every acre irrigated, or at the option of the purchaser, a charge not to exceed 20 cents per acre foot may be made for each and every acre foot delivered by the second party at th request of such purchaser.

INCREASE OF CAPACITY OF CANAL

Eleventh: The party of the second part shall be entitled at any time within five years from the date hereof to increase the appropriation of water from Snake River at the said dam hereinbefore described, to increase the capacity of said canals or either of them or any lateral thereof, and to use the same so enlarged or increased for the purpose of carrying any water belonging to the said party of the second part under such additional appropriation, provided, however, that such use shall be allowed only upon the making of such reasonable arrangements as to the expense of and care and maintenance of the canals and irrigation system, as may be agreed upon between the said party of the second part and the said Twin Falls Canal Company, Limited, whenever said last named company shall take possession of the canal system and as shall be approved by said party of the first part. Any rights acquired by the party of the second part under the provisions of this section shall be at all times held, used and enjoyed subject and subordinate to the rights of the purchasers of water rights for the irrigation of lands as provided in this contract.

It is further agreed that the said party of the second part, for the purpose of raising funds to construct the said canal system may execute a mortgage or deed of trust upon all its rights which it has or may hereafter acquire by virtue of this contract to any third party, provided that such mortgage or deed of trust shall contain a clause requiring the trustee or mortgagee as the case may be, upon the payment to such mortgagee or trustee of the amount stipulated to be paid by any purchaser of water rights to thereupon give a full release to such purchaser for the amount of the water rights so purchased by him; such mortgage or deed of trust to be subject to the terms and conditions of this contract and receive the approval of the Attorney General of the State of Idaho. All payments upon water rights are to be made to the trustee or mortgagee, if any, but trustee or mortgagee may consent otherwise.

TRANSFER OF THE MANAGEMENT AND CONTROL OF SAID CANAL SYSTEM TO PURCHASERS OF SHARES

Twelfth: Said party of the second part covenants and agrees that until such time as the majority of the shares of the Twin Falls Canal Company, Limited, shall have been conveyed and transferred to the owners and holders of the land under said canal system, it will cause to be maintained, operated and kept in good repair the said canals and irrigation system, and that if at any time during said period, the proper revenue, tolls, and income of the said Twin Falls Canal Company, Limited, shall be insufficient for the purpose of maintaining, operating and keeping in repair, the said canals and irrigation system, and that if at any time during said period the proper revenue, tolls, and income to the said Twin Falls Canal Company, Limited, shall be insufficient for the purpose of maintaining, operating and keeping in repair all the irrigation works hereinbefore referred to, it will at its own expense, and without cost or charge to the said Twin Falls Canal Company, Limited, supply to the treasury of the said last named corporation the funds necessary to supply such deficiency.

COMPLETION OF THE CANAL SYSTEM

Thirteenth: Said party of the second part agrees to begin work on said dam and canals and irrigation system within six months from the date of this contract, and that at least one-tenth of the construction work shall be completed within two years from the date hereof, that the construction of said works shall be prosecuted diligently and continuously to completion, and that a cessation of work after the second year without the sanction of said Board will forfeit to the State all rights under this contract, and second party further agrees to have said canal system fully constructed and in operation in accordance with this contract on or before five years from the date of this contract. It is understood and agreed that upon completion of the dam hereinbefore provided, and upon the completion of any such portion or portions of the said canal and laterals as may be conveniently operated by said Twin Falls Canal Company, Limited, said party of the second part will, upon the completion of said portion or portions of the canal or canals or laterals and in advance of the completion of the entire canal system, turn over and deliver possesion of such completed portion to the said Twin Falls Canal Company, Limited, provided said last named company shall with the consent of the State Board of Land Commissioners be organized prior to the completion of the canal, to the end that as rapidly as may be, the operation, maintenance and control of the said canal and irrigation system may be placed under the control and in the possession of said last named company.

FORFEITURE

Fourteenth: The said party of the second part agrees that upon the failure on its part to begin the construction of the said canal within the time specified in this contract, or upon the failure to proceed with the work, as agreed upon in this contract, after receiving sixty days' notice from the Secretary of the State Board of Land Commissioners, the bond given to secure the strict performance of the agreement herein contained, together with any portion or portions of said canal that may have been constructed under the conditions of the contract, shall be at once forfeited to the said party of the first part, the State of Idaho, and that the said party of the first part, acting through its said Board of Land Commissioners, may declare the same forfeited and proceed to enforce said bond and to take possession of said canal and irrigation works, and all the rights the said party may have acquired therein, as provided in the Act of the Legislature of the State of Idaho first referred to in this contract.

ESTIMATED COST

Fifteenth: The estimated cost of the proposed irrigation works is One Million Five Hundred Thousand ($1,500,000.00) Dollars. It is understood and agreed that the existing law under which this contract is executed is as much a part of this contract as if specifically herein set forth.

DESCRIPTION OF LANDS

Sixteenth: The lands hereinbefore referred to being the lands donated by Act of Congress to the State of Idaho under and pursuant to the Act approved August 18th, 1894, commonly called the "Carey Act," the reclamation and irrigation of which lands this contract is especially designed to effect, are duly set forth and described in a list hereunto attached and made part of this contract marked Exhibit C.

IN WITNESS WHEREOF, the said party of the first part, the State of Idaho, has by resolution of its State Board of Land Commissioners caused this agreement to be signed in duplicate by its Governor, attested by its Secretary of State, and the Great Seal of said State to be affixed hereto, and the said party of the second part has hereunto caused its corporate name to be attached by its President and attested by its Secretary, and its corporate seal to be affixed, as well as on the duplicate hereof, the day and year first above written.

(SEAL)

For the State of Idaho,
By F. W. HUNT, Governor.

Attest:
CHAS. J. BASSETT, Secretary of State.

THE TWIN FALLS LAND AND WATER COMPANY,
By S. B. MILNER, President.

(SEAL) Attest:
HARRISON E. JENKINS, Secretary.

Boise, Idaho, March 29, 1911.

State of Idaho, } ss.
County of Ada, }

I, N. Jenness, Register of the State Board of Land Commissioners of the State of Idaho, do hereby certify that the foregoing and hereto attached instrument is a true and correct copy of the contract between the State of Idaho and the Twin Falls Land and Water Company, as same appears of record and on file in my office.

IN WITNESS WHEREOF, I have hereunto set my hand and official seal this 20th day of March, 1911.

N. JENNESS, Register.

NAME OF APPLICANT.....

Form No. 0

SCALE: 2 Inches Equal 1 Mile. Draw Plan in Ink.

trol the said canal system there shall be delivered through the canals and laterals the water flowing therein equally and proportionately according to the representative rights of the parties entitled thereto.

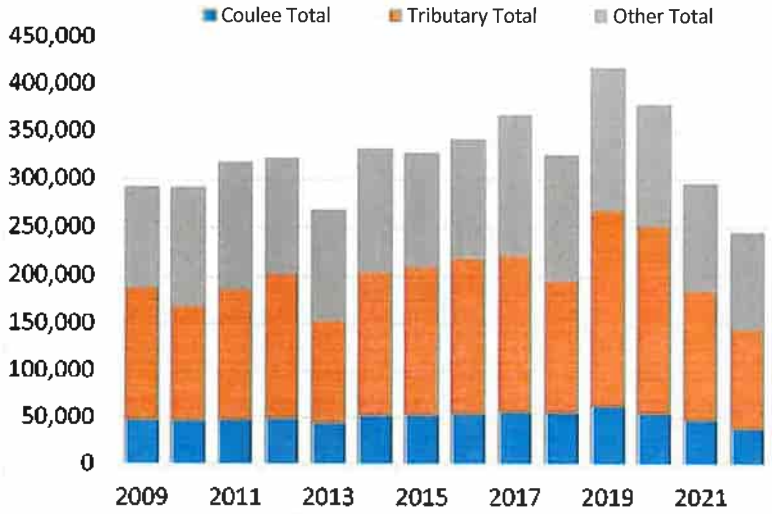
Any and all deferred payments for the purchase price of water rights or shares of stock may be secured by express contract of the purchaser pledging the water right or stock sold together with any and all rights in the lands to which the water is to be applied and the lien thereby granted shall be in addition to all liens granted by the laws of Idaho.

WATER RIGHT DEDICATED

Ninth: The certificates of sale of water rights and the certificates of shares of stock of the Twin Falls Canal Company, Limited, shall each upon being issued to the purchaser or holder of land under the canal system, be made to indicate and define in the contract or certificate as the case may be, the amount of water, to-wit: One eightieth of a second foot allotted to each acre represented thereby, and carrying capacity of the canal sufficient therefor, the water to be delivered from the canal during each and every irrigation season, said amount to be measured at or within one-half mile of the place of intended use in such quantities and at such times as the condition of the soil, crops and weather may determine but according to such rules and regulations based upon a system of distribution of water to the irrigators in turn and by rotation as will best protect and serve the interests of all the users of water from this canal system. It is agreed that said system of distribution by rotation shall be devised by the said party of the second part and used by it during the period while it retains the management of said system, and that it shall meet the approval of the State Engineer.

The sale or contract of the water right to the purchaser shall be a dedication of the water to the land to which the same is to be applied, and the water right so dedicated shall be a part of and shall relate to the water right belonging to the said system of canals.

All deeds for water rights if any be issued by the said second party, shall be based upon this contract, and shall meet the approval of the said party of the first part, the State of Idaho.



MEASUREMENT OF WATER CHARGES FOR DELIVERY

Tenth: The said party of the second part agrees to construct and until it shall convey and turn over the title and possession to the Twin Falls Canal Company, Limited, to operate said canal and main laterals so that water conducted through the same may be delivered at a point not exceeding one-half mile from any legal subdivision of one hundred and sixty acres of land herein described, filed upon, owned or oc-

Expert Report Regarding Selected Technical Aspects of the *Fifth Amended Final Order Regarding Methodology for Determining Material Injury to Reasonable In-Season Demand and Reasonable Carryover*

May 31, 2023
Bryce A. Contor
Principal Hydrologist
Rocky Mountain Environmental Associates, Inc.

Introduction

To aid in an administrative hearing concerning the *Fifth Amended Final Order Regarding Methodology for Determining Material Injury to Reasonable In-Season Demand and Reasonable Carryover* (Fifth Order), Rocky Mountain Environmental Associates Inc. (RMEA) provides this expert report regarding technical topics. This is not an exhaustive report, but is confined to the following technical issues:

- Technical arguments used by the Idaho Department of Water Resources (IDWR) to justify the use of transient modeling as opposed to stead state modeling;
- Purposes of the Enhanced Snake River Plain Aquifer Model (ESPAM) and technical opinions regarding its use;
- Possible application of source water fraction methods to parse out supplemental water use by the Surface Water Coalition;
- Logical consistency in the use of transient and steady-state modeling.

In this report, all references to Finding(s) of Fact or Conclusion(s) of law are to the Fifth Order unless explicitly stated otherwise.

Technical Arguments for use of Transient Modeling

Perhaps the most influential change in the Fifth Order is the change from steady-state modeling to transient-state modeling in determining a priority date for curtailment. The Fifth Order provides the following technical rationale for the change to transient modeling:

1. Page 2, last paragraph of the "Background" section states, *"the Department now has multiple years of experience with the methodology to better understand the impact of applying steady-state modeling versus transient modeling…."*
2. Also on page 2, the Fifth Order states *"The first version of the ESPA groundwater flow model was not calibrated at a time-scale that supported in-season transient modeling. In contrast, the current version [of ESPAM] was calibrated using monthly stress periods and half-month time steps, a refinement that facilitates in-season transient modeling…"*
3. Finding of Fact #83 quotes the Merriam-Webster dictionary for a plain-language meaning of the term "steady state," then asserts that *"A steady-state ESPAM simulation can only model [effects]… resulting from continuous curtailments of an identical magnitude and location until the effects of curtailment are fully realized."* Finding of Fact #84 states: *"For the benefits of curtailment predicted by steady-state analysis to be realized by the river, the curtailment must occur continuously until steady-state is achieved."*

Each of these stated rationales is discussed in turn, followed by a general conclusion.

Multiple Years of Experience

Concerning the stated reason that *"the Department now has multiple years of experience with the methodology to better understand the impact of applying steady-state modeling versus transient modeling,"* the Snake River Plain Aquifer Model Scenario: Hydrologic Effects of Curtailment of Ground-water Pumping Using Snake Plain Aquifer Model Version 1.1 "Curtailment Scenario" (Scenario) presented to IDWR in 2006 all of the implications of steady-state modeling vs transient described in the Fifth Order, that are correct. No data or modeling advances since 2006 have qualitatively changed the results of the Scenario. In the following excerpts, quotes from the Scenario are in italics, with square brackets *[ ]* showing clarifications that are compatible with the original text and analysis. Non-italic type not set off with brackets is commentary added with this report:

> *Page3: "It is important to recognize that even after curtailment of ground-water rights, there is a residual impact to river reaches due to previous years of ground-water pumping. The magnitude and timing of this residual impact can also be evaluated using these scenario simulations.*
>
> *Page 3: "The specific objectives [of the Scenario] are to:*
> *1) Determine the magnitude of increase in spring discharges and river gains over time for each sub-reach of the Snake River.*
> *2) Determine the seasonal magnitude of the expected increases.*
> *3) Determine the predicted impacts to aquifer water levels."*
>
> *Page 3 and page 4: "Initially, ground-water pumping removes water from aquifer storage, causing a localized cone of depression. As pumping continues, the effects propagate until a hydraulically connected boundary is reached. A recharge boundary will act as a source for the water being removed via ground-water pumping. Changes in*

EXHIBIT "500"
Page No. 2 of 33

aquifer water levels will impact the amount of water being recharged or discharged from a hydraulically connected recharge or discharge boundary. For example, in a hydraulically connected river reach, the relationship between river stage and aquifer water level will determine the amount of water moving between the aquifer and the river. For a gaining river reach, a decrease in aquifer water level will result in a decrease in the rate of ground-water discharge to the river....

As time passes and the collective impacts of ground-water pumping on the eastern Snake River Plain propagate throughout the aquifer system, less of the removed water is coming out of aquifer storage and more is coming from the river, either in the form of reduced spring discharges, decreased aquifer discharges to the river, or increased losses from the river. Ultimately, however, all of the ground water pumped and consumptively used for irrigation will come from the Snake River. It is difficult to quantify the volume and timing of these impacts to the river reaches. A numerical ground-water model is the best available tool for such an estimation."

Page 5 and 6: "The numerical superposition version of the ESPA model [used in the Scenario] is very similar to the fully populated ESPA model with all recharge and discharge terms removed and with a zero initial gradient. The numerical superposition model uses the concepts of superposition as detailed in Reilly and others (1987). The fundamental basis of superposition theory is that, for a strictly linear system, a complex problem can be decomposed into more simple sub-problems. The sum of the solutions of the sub-problems will be the same as the solution to the whole, more complex problem....

Confined aquifer model representations are strictly linear; unconfined aquifer model representations are non- linear due to the fact that aquifer transmissivity changes as aquifer water levels change. In the eastern Snake River Plain aquifer, the changes in water levels are very small relative to the total saturated thickness, so these nonlinearities are considered negligible. A comparison of the confined version of the ESPA model versus the unconfined version has been done by IWRRI and is published in ESPAM Design Document DDM-019, <u>Comparison of Unconfined and Confined Aquifer Representation</u>. Similarly, a comparison of model results using the fully populated model versus the numerical superposition model has been done by IWRRI and will also be documented in a report. The results of these evaluations support the conclusion that the non- linearities of the ESPAM are negligible. These results have been presented to the ESHMC [Eastern Snake Hydrologic Modeling Committee]....

The results from this [superposition] simulation represent the impacts from the particular aquifer stress being evaluated in isolation of all other recharge and discharge."

Page 6: "Evaluation of the impacts of curtailment of ground-water pumping was greatly facilitated by using the numerical superposition model. The numerical superposition model is not restricted to the 22-year period of the fully populated model and the effects of curtailment can be evaluated in isolation of all other recharge and discharge, yielding an estimate of expected <u>changes</u> in river gains and spring discharges due to curtailment. Evaluations of the results of these scenarios using numerical superposition can be used

EXHIBIT "500"
Page No. 3 of 33

to estimate expected future impacts to river gains due to curtailment and the residual impacts to river gains from ground-water pumping after ground-water curtailment. Using superposition allows analysis of the future impacts of a specified stress (in this case, ground-water pumping) without requiring knowledge of other future conditions such as weather" (emphasis in original).

Page 7: "For the long-term curtailment assessment, the annual averages of precipitation and evapotranspiration were used. For the seasonal curtailment assessment, summer and winter (corresponding to irrigation season and non- irrigation season) averages were used."

Page 8: "Additionally, Table 1 lists the time for each reach to come within 10% of the steady state value. For example, in Table 1, curtailment of all ground water is predicted to cause a 298 cfs accrual in the Devil's Washbowl to Buhl reach. Transient simulation results indicate that it would take approximately 59 years for the recovery to reach 90% of the steady state value. Similarly, curtailment of ground water junior to January 1, 1973 is predicted to cause an 88 cfs recovery in the same reach. Ninety percent of this recovery would be realized in 51 years."

Page 9: "Table 2 summarizes the predicted reach accrual after one year of curtailment for each reach for each cutoff date." Unfortunately, the units of Table 1 are "cfs" and the units of Table 2 are "acre feet," so it would take some calculation to perceive the difference between the first-year results and the total result.

Page 10: "Figures 18 through 28 show the seasonal predictions of reach accruals for the 11 reaches of the Snake River for each of the five cutoff priority dates....

Many of the reaches... show a winter decline almost back to the river reach gain levels of the previous year. Some of the reaches, however, show a smaller decline relative to the predicted accruals. This would indicate that the curtailed areas are more distant from the reach and that the accruals are taking longer to get to the reach...." Figure 18 also shows single-year results for two of the cutoff dates.

EXHIBIT "500"
Page No. 4 of 33

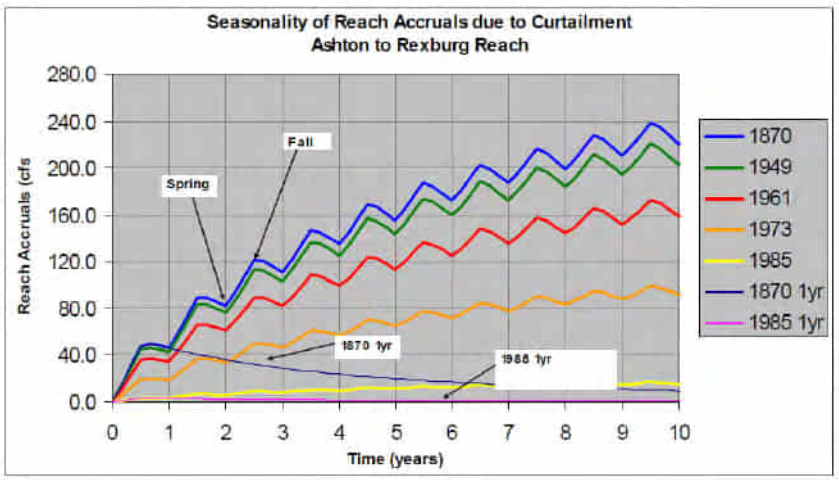

Figure 18. Seasonality of Reach Accruals due to Curtailment of Ground-Water Pumping for Ashton-Rexburg Reach (generated using ESPAM v1.1).

Figure R1: Figure 18 reproduced from Scenario.

Page 11: "Just as curtailment of ground-water pumping will cause increases in river gains, curtailment will also cause a recovery of aquifer water levels. Figures 29 through 34 show predicted changes in water levels at six locations throughout the plain due to curtailment of all ground-water pumping." Page 11 also states *"The magnitude of the rise is driven by how proximal the curtailed ground-water irrigated lands are to the river reach under evaluation."* This is incorrect and should read "how proximal... to the location where water-level changes were considered."

EXHIBIT "500"
Page No. 5 of 33

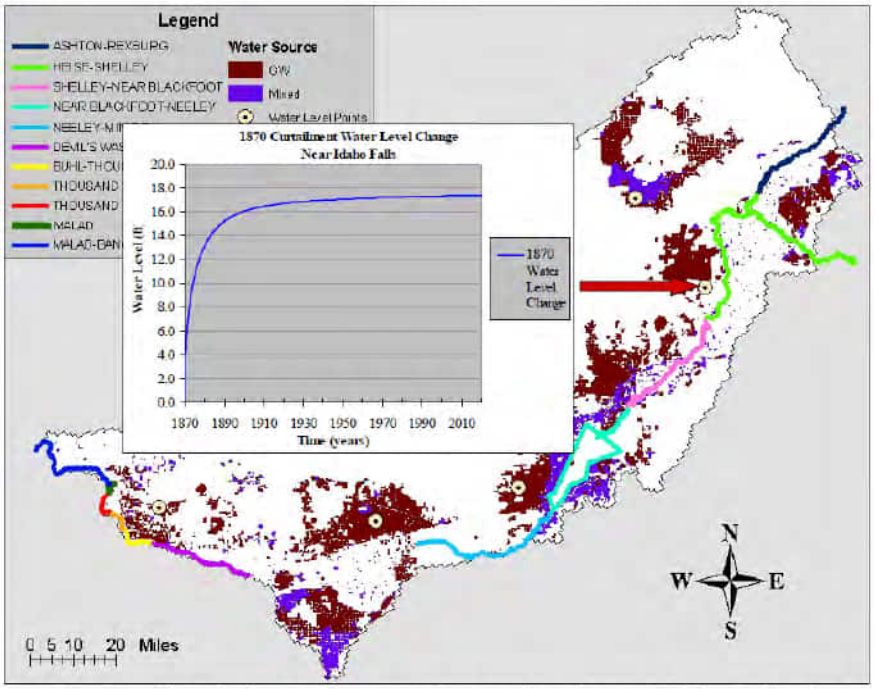

Figure 30. Predicted change in ground water level near Idaho Falls due to curtailment of ground water pumping junior to 1870 (generated using ESPAM v1.1).

Figure R2: Figure 30 reproduced from Scenario.

> *Page 11: "For the temporary, 1-year simulation, maximum realizable accruals are relatively small but the benefits last for several years."*

These excerpts show the state of knowledge that has been available to IDWR since 2006. It could be argued that a 2006 report is so old that no IDWR personnel who were familiar with it were involved with technical input to the Fifth Order. However, a 2013 staff memo from Jennifer Sukow to Gary Spackman indicates that in 2012 Sukow repeated the curtailment scenario exercise using both ESPAM2.0 and ESPAM2.1. It is clear that in 2012 Sukow was aware of the 2006 work, and that Spackman had an opportunity to be aware of it at least as early as 2013. Both still are employed at IDWR and could have applied this knowledge at any time in approximately the last decade.

Modeling Time Scale

The second stated reason is that the *"first version of the ESPA groundwater flow model was not calibrated at a time-scale that supported in-season transient modeling. In contrast, the current version [of ESPAM] was calibrated using monthly stress periods and half-month time steps, a refinement that facilitates in-season transient modeling…."* A stress period in modeling parlance is a representation of a period of time during which model inputs (recharge and

EXHIBIT "500"
Page No. 6 of 33

discharge data, and calibration targets) are held constant. Table 1 in this report shows the date of release and stress period lengths used in the various versions of the model discussed above. The timing of events shown in Table R1 is different than intimated by the statement in the Fifth Order.

Table R1. Model Versions, Report Dates, and Stress-Period Lengths

Model	Report Year	Stress-Period Length
SRPAM	1999	15.2 days
ESPAM1.0	(no report)	6 months
ESPAM1.1	2006	6 months
ESPAM2.0	(no report)	1 month
ESPAM2.1	2013	1 month
ESPAM2.2	2021	1 month

In addition to the fact that ESPAM modeling with one-month stress periods precedes the 2016 Fourth Methodology order by three years, the notion that earlier versions did not facilitate ***"in-season transient modeling"*** should be considered in light of the following:

- The 1999 SRPAM stress period was shorter even than the ESPAM2.2 stress period.
- The 2005 – 2006 ESPAM1.0 and ESPAM1.1 stress periods were approximately the length of an irrigation season and were assigned to winter and summer months in a fashion that facilitates evaluation of effects upon surface-water irrigation supplies.
- As illustrated by the Scenario, the ESPAM1.0 and ESPAM1.1 models not only were explicitly designed to represent seasonal effects of activities, they were used for that purpose at least as early as 2006.
- It is not necessary for the stress-period length in model application to match the stress-period length in calibration, as demonstrated by all versions of the IDWR transfer tool (ETRAN).

It is acknowledged that generally it is not considered good modeling practice to apply the model with shorter stress periods than used in calibration, though this guideline was not adhered to in the first single-cell versions of IDWR's transfer tool.

Time constraints precluded more robust analysis, and precluded analysis using ESPAM2.2. However, a limited analysis was conducted using a monthly version and a trimester version of ESPAM2.1, at three of the points shown in Figure R3. These points were not selected to be representative but rather to fully explore differences across the aquifer.

The monthly version of ESPAM2.1 is referred to as "RSP_E2_1." It is a proprietary tool developed by Rocky Mountain Environmental Associates that uses a mathematical modeling procedure called ***convolution*** to apply a table of input stresses to a large database (approximately two gigabytes) of transient response functions that provide responses from each of approximately 11,000 model cells to each of approximately 60 modeled spring and river reaches. The trimester version is IDWR's "ETRAN3.3" transfer tool.

EXHIBIT "500"
Page No. 7 of 33

For each point, the model was applied three times; once with ETRAN3.3, and twice with RSP_E2_1. Results are illustrated in Figure R4 through Figure R6. Only the first two years of results are shown, and only for the Near Blackfoot to Minidoka reach. All three applications represented a curtailment event that would produce 100 acre feet of reduction at the modeled point. For the results labeled "Trimester," the 100 acre feet were applied uniformly across one four-month trimester, and results modeled on a trimester stress period. For results labeled "Monthly 1," the 100 acre feet were applied uniformly across the first four months, so the application of effect was identical to the "Trimester" rendition. However, the modeling used one-month stress periods. The "Monthly 2" results also reflect 100 acre feet of relief modeled using one-month stress periods, but the relief was applied variably across six months in an effort to simulate the approximate timing of relief from an actual curtailment event.

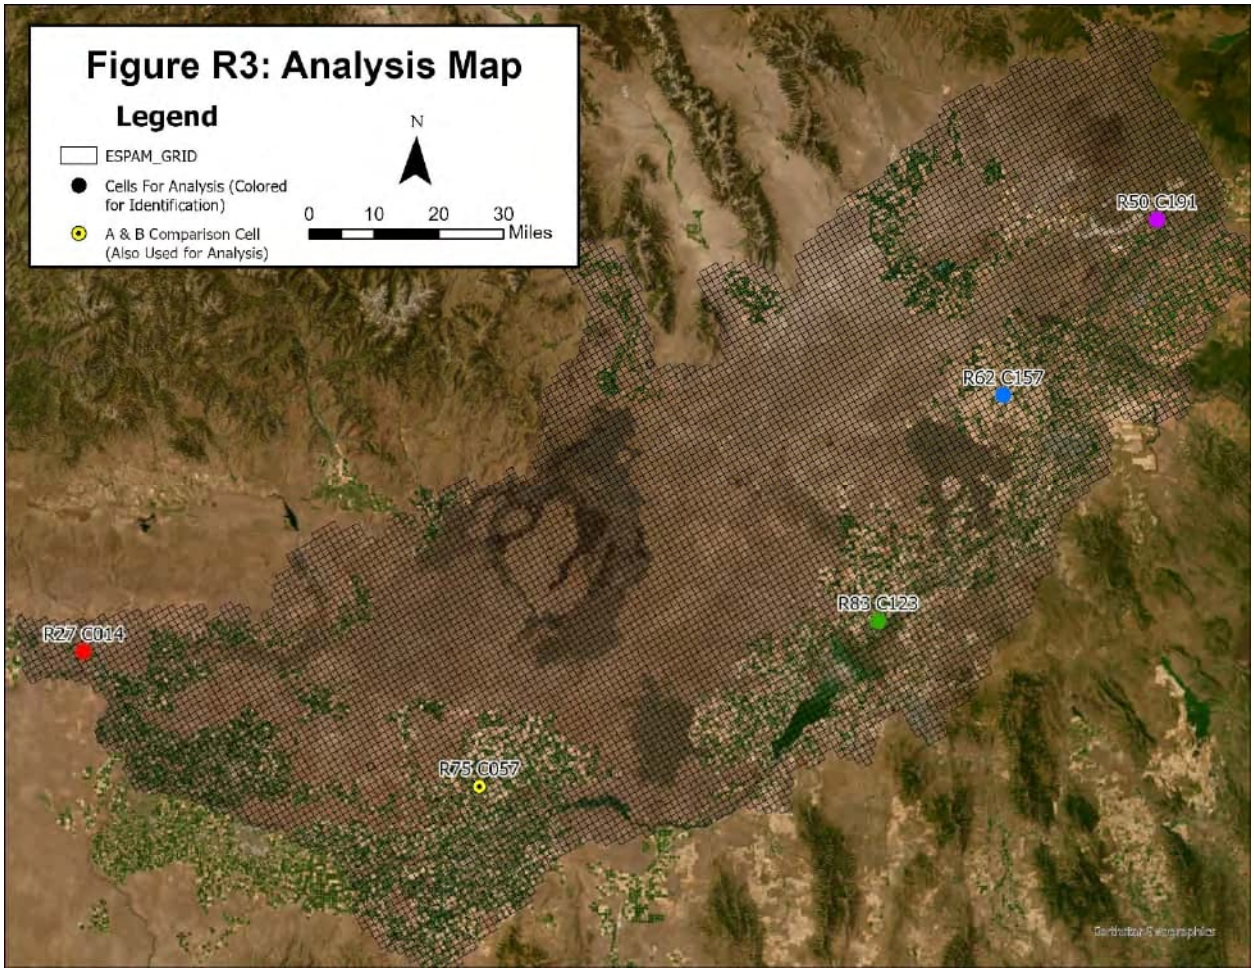

Figure R3.

EXHIBIT "500"
Page No. 8 of 33

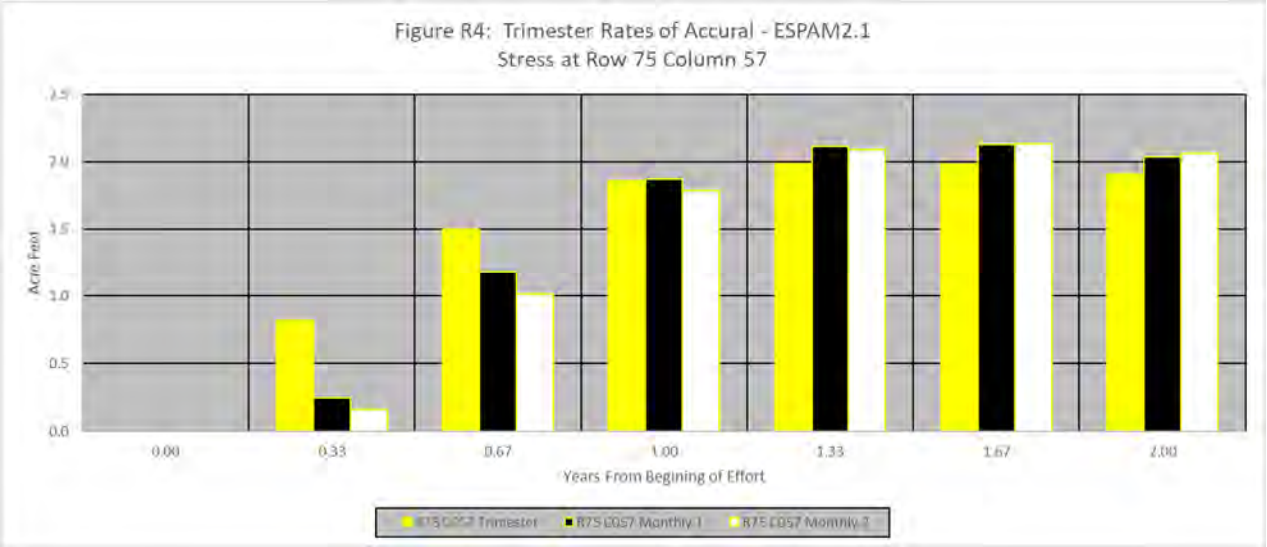

Figure R4.

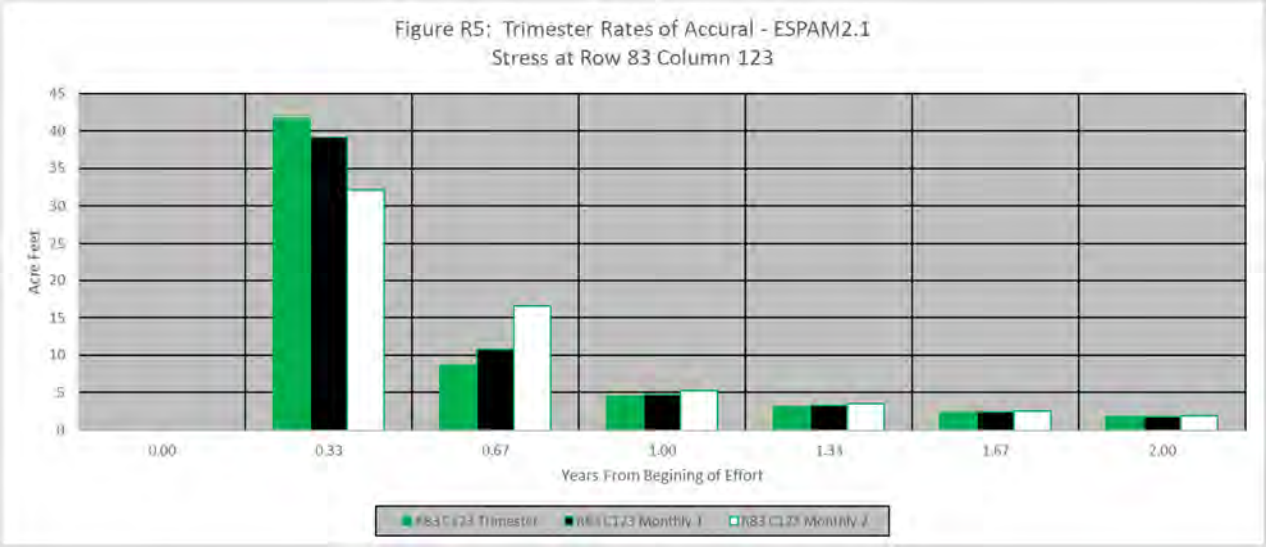

Figure R5.

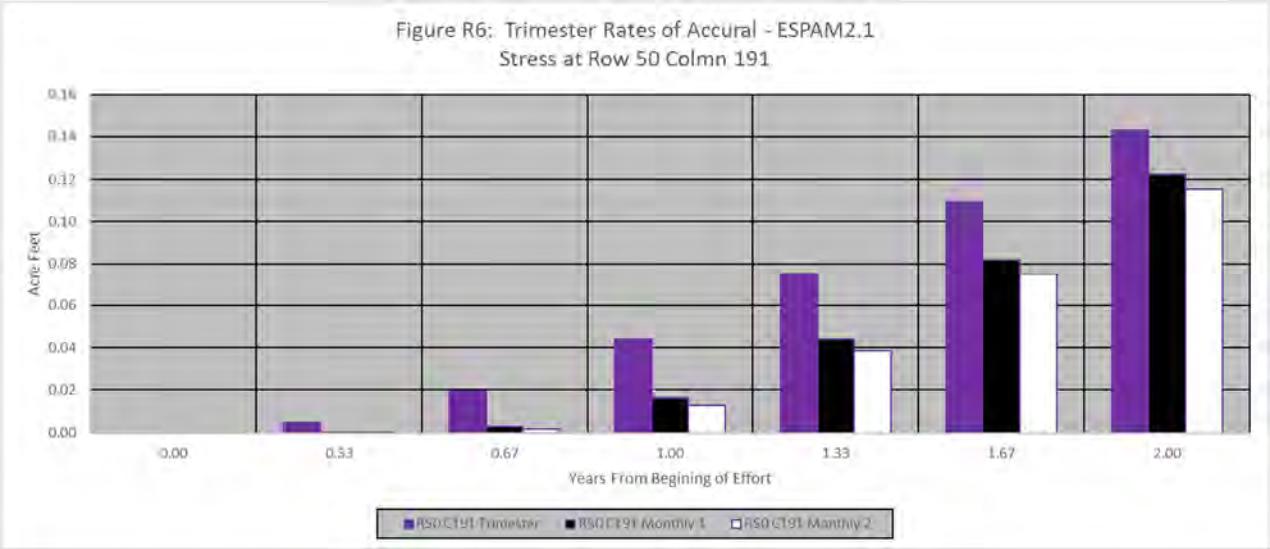

Figure R6.

Conclusions from this limited exercise are as follows:

- Within the first two years, results are qualitatively similar but not quantitatively identical.
- The differences resulting from stress-period length and temporal description of the effect of curtailment subjectively appear to be smaller than the differences between successive versions of the model, as discussed later in this report.
- The largest discrepancies, in terms of percent difference between model outputs, were observed in the point that showed the smallest overall response to the Near Blackfoot to Minidoka reach. Time constraints precluded exploration of whether this is a general result.

The results may be somewhat misleading; the model can be set to produce results as of the beginning of a stress period, or as of the end. Time constraints did not allow exploration of whether the RSP_E2_1 and ETRAN3.3 were consistent in this setting. If they were not, the discrepancies may be smaller than the figures suggest. Nevertheless, the overall conclusion is that monthly stress periods are somewhat different, and perhaps "better," than longer stress periods, but that four month stress periods and by extension probably six month stress periods can be used for evaluation on the time frame of individual irrigation seasons, as intended and practiced with ESPAM models prior to 2013.

The Nature of Steady-state Modeling

The third stated technical reason to adopt transient modeling is that *"A steady-state ESPAM simulation can only model [effects]… resulting from continuous curtailments of an identical magnitude and location until the effects of curtailment are fully realized."* It is true that permanent curtailment *could* be a presumption of steady-state analysis, and this could be the

EXHIBIT "500"
Page No. 10 of 33

presumption that was made in constructing the Scenario in terms of cubic feet per second, as suggested by the following quote:

> *Page 8: "The steady state analysis presumes the unlikely case that pumping has been permanently curtailed."*

If this was meant to apply generally to steady state modeling, it is incorrect, though it may be a reasonable explanation for a model run whose input and output values were contemplated in terms of flow rate (cfs). If the input and output values were contemplated in terms of acre feet (as is done in assigning a curtailment date), a more correct statement would have been that "Steady state analysis estimates only where the effects of curtailment will accrue and provides no information on the timing of curtailment or accrual." The most striking example of this fact is that steady-state modeling has been used to calculate curtailment date under all prior methodology orders, and is used in the Fifth Order to partition mitigation responsibility.

Despite the incorrect, or at best unfortunate, wording in the Scenario, its results did show that at long time periods, transient modeling very closely approximates time-agnostic steady-state modeling:

> *Page 9: "Figures 7 through 17 show the predicted reach accruals over a long period of time for each modeled reach, for each cutoff date..... Each figure also shows the steady state value for predicted accruals for each of the cutoff dates."*

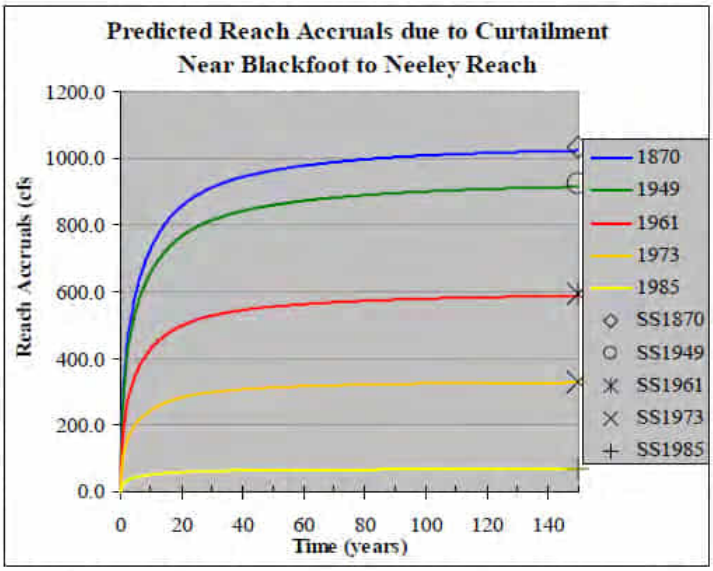

Figure 10. Predicted Reach Accruals due to Curtailment of Ground-Water Pumping for Near Blackfoot-Neeley Reach (generated using ESPAM v1.1).

Figure R7: Figure 10 reproduced from Scenario.

Intuitively, and as explained in the Scenario in 2006, if the modeling period is sufficiently long

EXHIBIT "500"
Page No. 11 of 33

relative to the duration of the event and the proximity of it to springs and rivers, transient results will begin to approach steady-state results and would equal them if the transient simulation could be run to infinite time.

A technically-correct Finding of Fact #83 could read:

> *Merriam-Webster's Dictionary defines steady-state as "a state or condition of a system or process … that does not change in time." Steady state, Merriam-Webster.com, https://www.merriam-webster.com/dictionary/steady-state (April 19, 2023). A steady-state ESPAM simulation based on input values of acre feet of curtailment can only ~~model increases in aquifer discharge~~ indicate total acre feet of accrual to modeled reaches of the Snake River and tributary springs resulting ~~from continuous curtailments of an identical magnitude and location until the impacts~~ after the effects of curtailment ~~are~~ have fully been realized. For example, a steady-state analysis of the curtailment of 1,000 acre feet would indicate where the 1,000 acre feet of accrual eventually would be expressed, but would not describe the timing of arrival of accruals. ~~acres, assumes that irrigation of the same 1,000 acres is curtailed every year at the same rate of consumptive use, until the impacts of that curtailment reach a steady state, or no longer change from year to year~~.*

A technically-correct Finding of Fact #84 could read in part:

> *Steady-state analysis does not calculate the time to reach steady-state conditions nor describe the seasonal timing of the impacts, but only estimates the spatial distribution of accruals. To estimate the timing of accruals, transient modeling must be employed. ~~For the benefits of curtailment predicted by steady-state analysis to be realized by the river, the curtailment must occur continuously until steady-state is achieved. The assumption of continuous curtailment does not reflect reality in the SWC Delivery Call~~* [SWC refers to the Surface Water Coalition].

Conclusions Regarding Technical Justification for Adopting Transient Modeling

It is my professional opinion that the Fifth Order's technical arguments for adoption of transient modeling are not factually sound:

- IDWR has had access to the current understanding of the general implications of transient vs. steady-state modeling since at least 1999, and access to the specific implications of a curtailment context since 2006;
- The 1999 SRPAM model had stress periods even shorter than the current model;
- Though its stress periods were longer than the current model, the 2006 ESPAM1.1 model was designed and deployed to represent effects on an irrigation-season time scale;
- The 2013 ESPAM2.1 model had identical stress periods to the current ESPAM2.2 model.
- The transient version of the model can be used to represent temporary curtailment of water rights.

EXHIBIT "500"
Page No. 12 of 33

Since the technical rational presented is not factually correct, it is my professional opinion that the Fifth Order does not reveal the true rationale for the change from steady-state to transient. I therefore am unable to comment on the technical merit of the actual rationale.

Purposes and Use of ESPAM Modeling

The 1999 SRPAM model was stated "*to be a planning and management tool for use by both agencies [IDWR and US Bureau of Reclamation]*. The subsequent ESPAM model reports have indicated the stated purpose of informing *"conjunctive management,"* a misnomer that has been used for decades in Idaho for conjunctive ***administration*** of groundwater and surface-water rights. Curtailment is a conjunctive-administration activity, and in all likelihood, curtailment calculations always have been a consideration of IDWR. However, the ESPAM reports have cautioned that model use should correspond to its regional nature; for instance, from the ESPAM2.2 report: *"The [model] is a regional groundwater model. For this reason, the model is best used for broad-scale predictions. The user should avoid the temptation to model localized phenomena…. This limitation exists in part because the input data used to compute the agricultural impacts are still coarse."*

In 2007 and again in 2012, many members of the Eastern Snake Plain Hydrologic Modeling Committee (ESHMC) responded to invitations to participate in drafting of "white papers," which in reality were compilations of individual statements on model use. Opinions ranged widely, from: "*It is our professional opinion that the current model has no technical credibility as a tool for water rights administration*" (2007 White Paper) to: *"[I]nformation from the model can be used to estimate the effects of curtailment of ground water pumping on aggregated river reaches."* (2007 White Paper).

An especially insightful comment elaborates on the caution regarding coarse data: *"The effects of temporal imprecision are analogous to the effects of spatial imprecision, but are compounded with concerns about the difficulty the calibrators have had in matching seasonal amplitude in some target springs. These suggest to us that while the model <u>can</u> be used to estimate effects on a monthly basis, it <u>should not</u> be used to make administrative decisions that hinge on monthly distribution of effects"* (2012 White Paper contribution from Eastern Idaho Water Rights Coalition, emphasis in original).

Implicit in using any tool for any purpose is a determination that the tool satisfies the minimum criteria for its use. Establishing criteria is a policy question, and whether criteria are met is a technical question. The Fifth Order does not describe the policy criterion for the model's ability to match month-to-month variation, nor the rationale for the criterion. However, a metric is available; the ESPAM2.2 report provides an R^2 score for each model reach, shown in the bottom right panel of the corresponding figure of calibration results. The R^2 statistic can be described as a score of the fraction of variability in a data set that are described by an algorithm and its input data. Figure 119 shows an R^2 value of 0.4232 (i.e. the model and its input data can explain approximately 42% of monthly variability) for the Near Blackfoot to Neeley reach, and Figure

EXHIBIT "500"
Page No. 13 of 33

120 shows an R^2 value of 0.0079 (under 1%) for the Neeley to Minidoka reach. The bottom center panel provides an indication of when in the year discrepancies generally occur; these are the months when the blue and orange lines are most disparate. In both cases, the average results are worst during the irrigation season.

It is my professional opinion that unless the criterion for the ability to match monthly values is very low, ESPAM2.2 likely should not be considered appropriate for estimating month-by-month effects for the combined Near Blackfoot to Minidoka model reach when substantial consequences depend on decisions made on its basis.

Technical work that could inform the policy decision of establishing a criterion would explore the ratio of the potential relief of curtailment to the known cost. Additional technical defensibility could be gained by holistically considering all the hydrologic implications of the fundamental differences in spatial and temporal responses between groundwater systems and surface-water systems, as discussed later in this report.

It is my professional opinion that the use of ESPAM modeling is technically defensible when ratios of relief to cost are considered in light of modeling precision and imprecision, and when policy adjusts for spatial and temporal responses. This is true for both steady-state and transient modeling analysis.

Supplemental Water Use by SWC

Finding of Fact #23 states: *"There are lands within the service areas of SWC entities that are irrigated with supplemental groundwater. Exhibit 3007. Supplemental groundwater is a factor the Director can consider in the context of a delivery call…. At this time, the information submitted or available to the Department is insufficient to determine the extent of supplemental irrigation on lands within the service areas of SWC entities."*

My professional opinion is that because this statement is not factually correct, the true rational for this decision has not been disclosed. Therefore, I cannot respond to the technical content of the actual rationale. The basis for this opinion is:

- Since the initial development of ESPAM1.0 in the early 2000s, the extent and effect of supplemental groundwater irrigation has been calculated for the parts of the SWC Service Areas that are within the ESPAM model boundary.
- The data and methods that have been used in the ESPAM model are readily available and applicable to the parts of the SWC Service Areas that are outside the ESPAM model boundary.
- As a result of measurement orders, the measurement and report of well discharge data, and the availability of these data in IDWR's Water Measurement Information System (WMIS) are much more robust than in the early 2000s when these calculations first were undertaken and the methods developed.

EXHIBIT "500"
Page No. 14 of 33

- IDWR has known, or could have known, since at least 2015 that these data would be important to a correct calculation of Reasonable In Season Demand. The intervening eight years would have been sufficient time to apply the existing data and methods, or to improve them, for purposes of the methodology.

Because of the existence of these methods and data, it is my professional opinion that a defensible adjustment for supplemental groundwater use within the SWC Service Areas is reasonably within reach, on a technical basis. The existence of these methods and data is documented in accompanying documents:

- Cosgrove, D.M., B.A. Contor and G.S. Johnson. 2006 Enhanced Snake Plain Aquifer Model Final Report, pages 50 – 54.
- Contor, Bryce A. and Paul L. Pelot. April, 2008. Draft 2. Determination of Source of Irrigation Water for Calibration of Eastern Snake Plain Aquifer Model Version 2.
- Idaho Department of Water Resources. 2013. Enhanced Snake Plain Aquifer Model Version 2.1 Final Report, pages 50 – 52.
- Sukow, Jennifer. 2021. Model Calibration Report Eastern Snake Plain Aquifer Model Version 2.2, pages 15 – 17.

In addition, substantially more acre feet of diversion are required to support a surface-water irrigated acre than a groundwater-irrigated acre because the curtailment requirement is multiplied by the following:

- An acre of groundwater irrigation requires fewer acre feet of gross diversion than does an acre of surface-water irrigation supplied by a long canal.
- For most groundwater-irrigated lands, more accrual from curtailment arrives at non-target reaches than arrives at the Near Blackfoot to Minidoka Reach
- The curtailment requirement again is multiplied by the fact that more accruals from curtailment occur in future years than in the year of need.

Thus, it is my professional opinion that neglecting a single acre of supplemental irrigation within the SWC Service Area results in needless curtailment of many groundwater-irrigated acres. Therefore, strictly on a technical basis, the refinement of quantifying the effect of supplemental irrigation within the Surface Water Coalition service area could provide substantial relief to a broad constituency of Idaho water users.

Logical Consistency

This section of the report addresses logical consistency in application of modeling, from a technical viewpoint. It also lays groundwork for an attempt to address a hearing officer's complaint from a number of years ago that expert reports tend to focus on what ***cannot*** be done, without providing a hearing officer any input on what could be done from a technical standpoint. In response to that complaint, this report concludes with a conceptual discussion of a technical

EXHIBIT "500"
Page No. 15 of 33

approach that is logically consistent and coherent, that could be considered as foundation for policy deliberations.

Accruals beyond the Irrigation Season

Finding of Fact #86 indicates that: *"Only 9% to 15% of the steady state response is predicted to accrue to the near Blackfoot to Minidoka reach between May 1 and September 30 of the same year,"* indicating that the bulk of accruals from curtailment do not arrive during the time period of indicated shortfall. Time constraints prevented confirmation of the numerical values, but conceptually this matches my understanding. However, the actual response time is independent of modeling and is governed by the physical properties of the aquifer/river system. While 9% to 15% probably is a reasonable estimate, whatever the true value is, it applies identically to any curtailment regardless of whether it was calculated using steady-state or transient modeling. The only difference is that the transient modeling produces an estimate of the delay in accrual.

The delay in accrual depends on the spatial relationship of the well curtailed and the reach for which accruals are desired. The spatial distribution of the delayed response from curtailment is illustrated using evaluation of the sample points illustrated in Figure R3, presented earlier. Spatial distribution is illustrated using results from the ETRAN3.4 Transfer Tool realization of the transient ESPAM2.2 model.

Time constraints precluded duplicating the five-month May 1 to September 30 period considered important in Finding of Fact #86. However, the ETRAN3.4 Transfer Tool four-month period is not too different, and allows conceptual discussion of the results shown in Figure R8 through Figure R13. Though the transfer tool assigns its summer trimester to July, August, September, and October, from my involvement in the development of the original transfer tool I know that this assignment is arbitrary and that it is valid to consider that the figures illustrate the results of a four-month curtailment beginning in May.

EXHIBIT "500"
Page No. 16 of 33

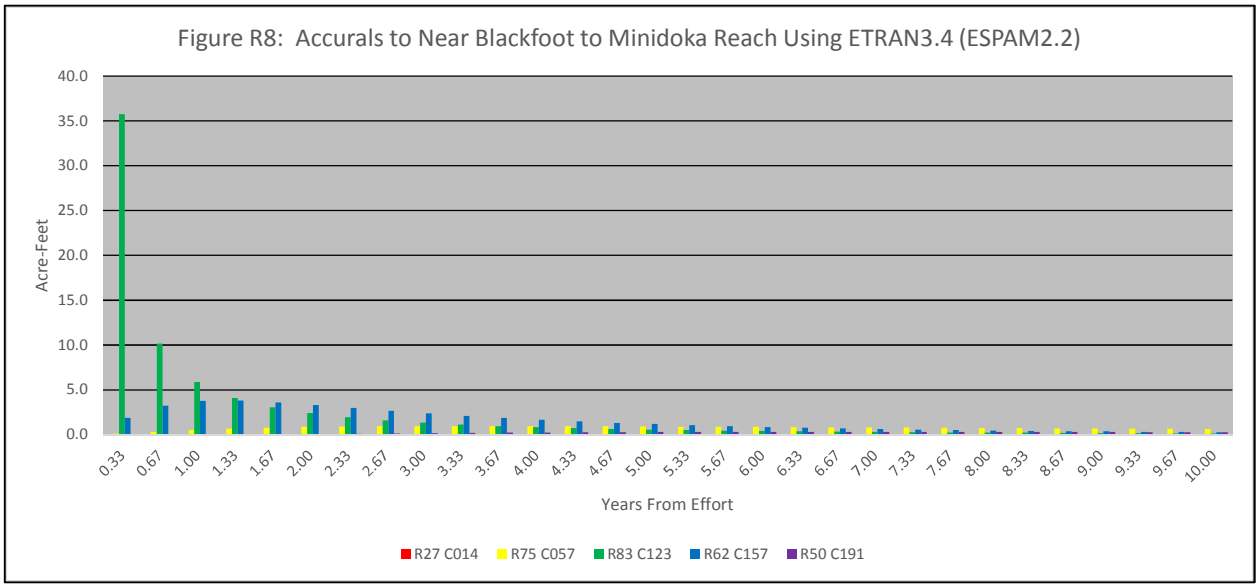

Figure R8.

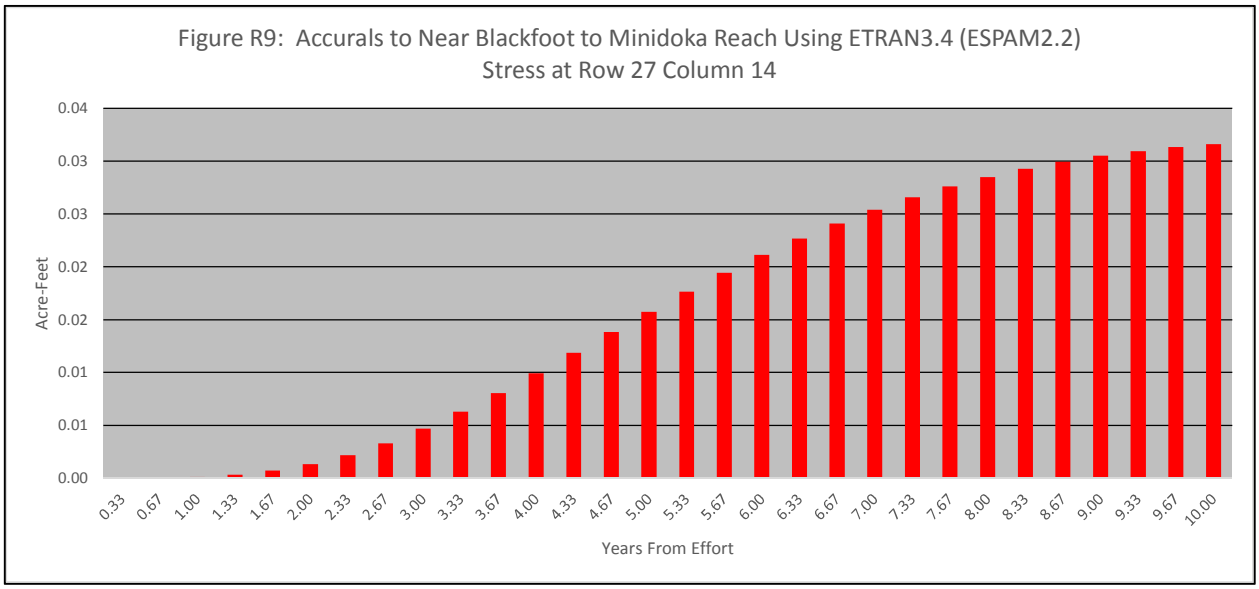

Figure R9.

EXHIBIT "500"
Page No. 17 of 33

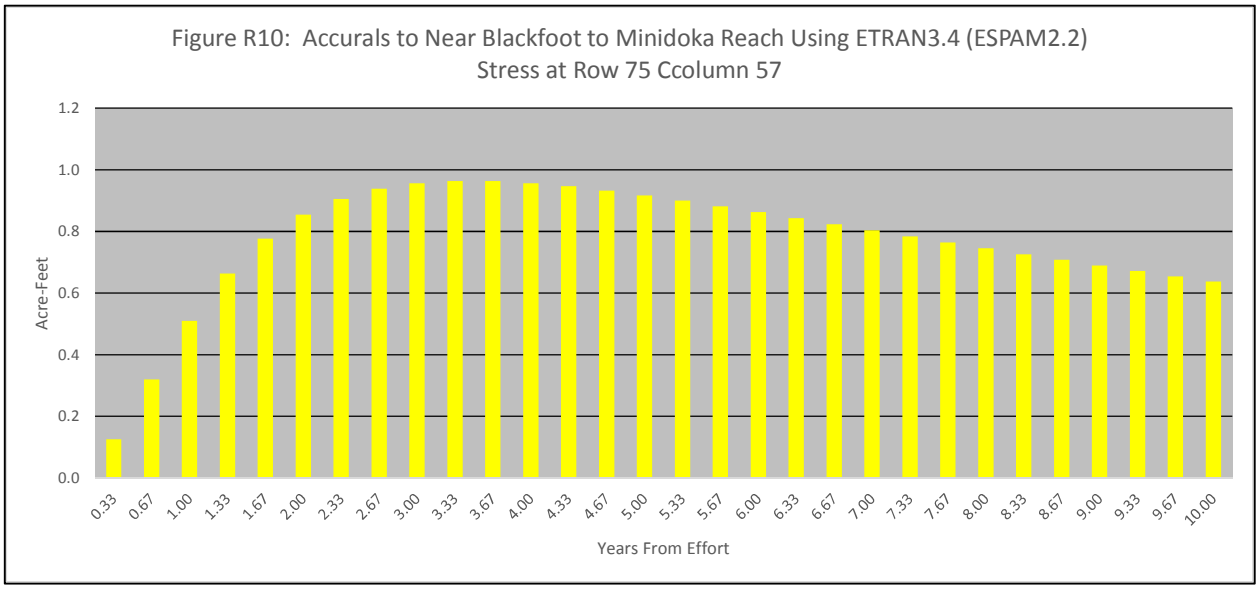

Figure R10.

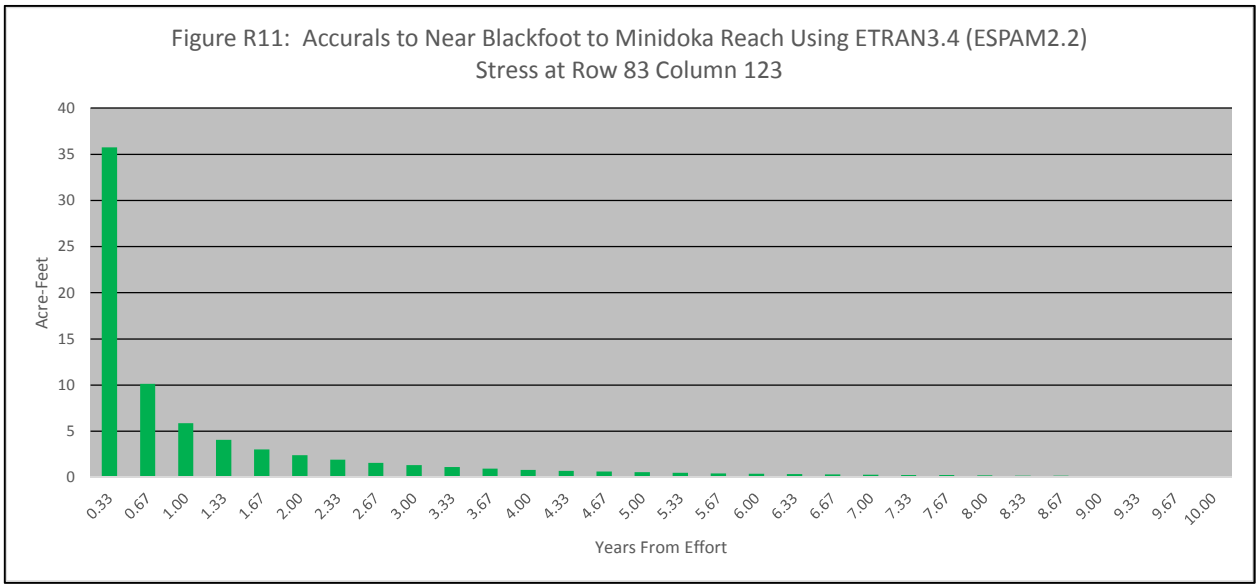

Figure R11.

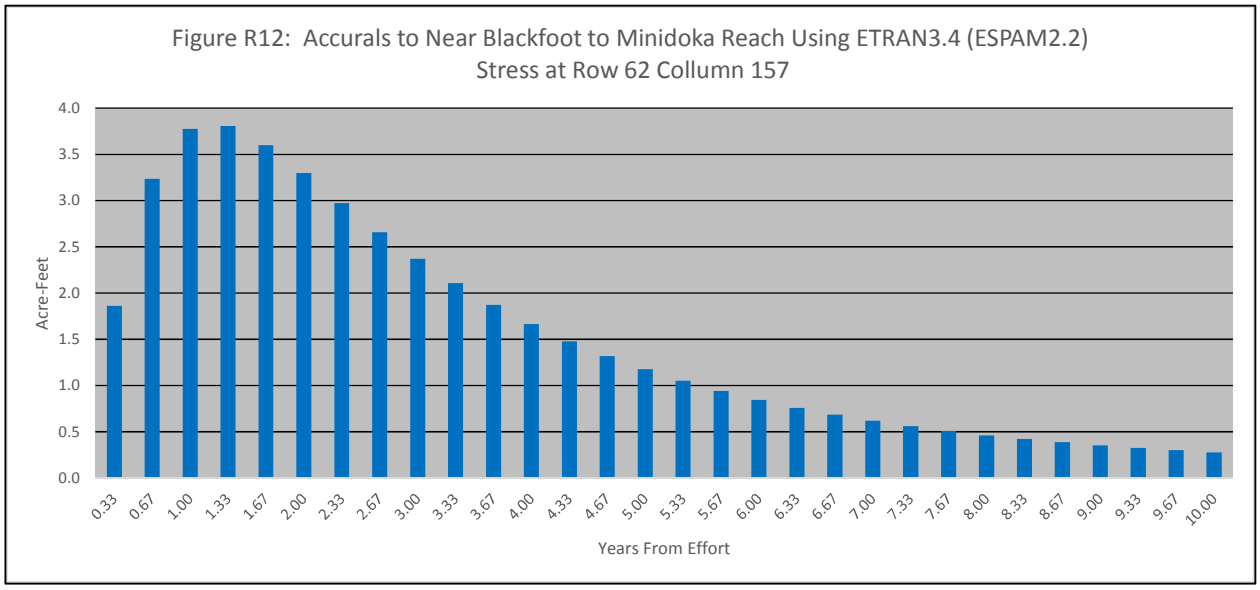

Figure R12.

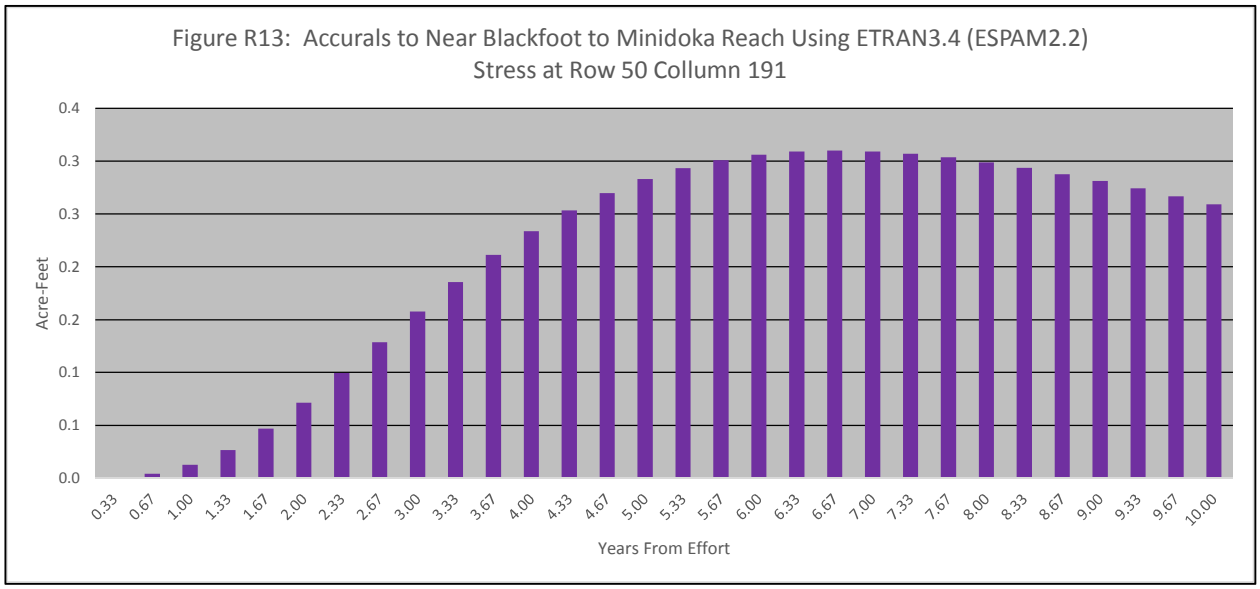

Figure R13.

Qualitatively, these figures can be summed up with the statement that: "Accruals from curtailment predominantly arrive in years later than the curtailment event, except for curtailment that occurs very near the river in the Near Blackfoot to Minidoka reach."

In deposition testimony in May, 2023, Jennifer Sukow of IDWR indicated her opinion that model-indicated future accruals to irrigation-season reach gains could be applied to offset future calculated shortfalls. This is logically consistent with the physical nature of propagation of effects, and with the modeling. However, because this carry-forward does not appear to be specified in the Fifth Order it is not clear whether such a carry-forward would be authorized. Additionally, earlier orders' Step 10, using transient modeling in relationship to reasonable

EXHIBIT "500"
Page No. 19 of 33

carryover, was remanded by the court (Fourth Methodology Order page 3). Time constraints preclude exploration of the arguments and rationale behind this remand, and without this understanding, it is difficult to assess whether Sukow's proposed carry-forward would survive judicial review. Regardless, even if the Fifth Order does would allow it, and even if it would survive judicial review, its omission from the Fifth Order leaves it as a mechanism that cannot be relied upon.

Sukow also indicated that the effect of curtailment on future carryover calculations would be implicit in the data relied upon. Though time constraints preclude a robust analysis, it appears that the assumption of the methodology calculations is that the data represent a single snapshot of time within a dynamic equilibrium. If this is true, then for Sukow's argument to be logically consistent, the implicit effect of prior curtailment on the well that is used in calculations would be expected to be dynamically stable, meaning that water level in said well would be relatively consistent over time. However, this is not the case following a one-time curtailment event, and the departure of the assumption from reality depends on the temporal and spatial distance of the curtailment event from the well, and also on its magnitude. Considering that modeled reach gains are a manifestation of aquifer heads in model river cells, the temporal aspects of effects on the well can be qualitatively compared to the model results summarized in Figure R8 through R13.

In Figure R11, early accruals are greater than subsequent accruals. This scenario reflects a curtailment that occurred relatively near the well, much as cell R83 C123 is relatively near the Near Blackfoot to Minidoka reach. Sukow’s implicit assumption would overestimate accruals during the second year after curtailment. Overestimates, such as this one, hurt the SWC by providing less during the second year than the model would suggest. Conversely, Figures R9, R10, and R13 show scenarios for locations more distant, where subsequent accruals exceed the initial accruals. In this case, Sukow’s implicit assumption would underestimate accruals during the second year after curtailment, harming potentially-curtailed water users by requiring more curtailment than is necessary to meet the need of a call. A solution would be to explicitly model and account for all future accruals, much as Sukow proposed for in-season demand calculations.

Accruals to Non-Target Reaches

The Fifth Order does not discuss the fact that curtailment would result in greater accruals to non-target reaches than it would to the Near Blackfoot to Minidoka Reach. Time constraints did not allow exploration of ESPAM2.2 results, but they would be qualitatively similar to the ESPAM1.1 results from Table 1 of the Scenario, reproduced here.

EXHIBIT "500"

Total (acre-feet/year)	**1,984,659**		**1,775,637**		**1,182,086**		**663,362**		**130,506**	

Figure R14: Table 1 reproduced from Scenario.

Extracting the Near Blackfoot to Neeley and Neeley to Minidoka results, and comparing them to the total results, indicates the relationships show in Table R2.

Table R2: Summary of ESPAM1.1 results from Scenario

	Near Blackfoot to Neeley Accrual (cfs)	**Neeley to Minidoka Accrual (cfs)**	**Near Blackfoot to Minidoka Accrual (cfs)**	**Total Accrual (cfs)**	**Percentage of Accrual to Near Blackfoot to Minidoka**
All Pumping	1,035	158	1,193	2,741	44%
Junior to January 1, 1949	925	134	1,059	2,453	43%
Junior to January 1, 1961	593	84	677	1,633	41%
Junior to January 1, 1973	331	46	377	916	41%
Junior to January 1, 1985	69	10	79	180	44%

Depending on viewpoint, the fact that more than half the accruals from curtailment arrive at non-target reaches is either a windfall or is collateral damage. Regardless, the Fifth Order is silent on the fact of the accrual and on the technical ability to assess and report its timing and magnitude

EXHIBIT "500"
Page No. 21 of 33

for potential application to needs that might arise in non-target reaches, such as the small amounts of additional accrual that sometimes are needed to facilitate a Point of Diversion transfer of a groundwater right.

Consistency between Calculation of Priority Date and Partition of Responsibility

In deposition testimony in May, 2023, Jennifer Sukow indicated that the partition of responsibility for mitigation in lieu of curtailment is done on a steady-state basis on the rationale that all users bear responsibility for cumulative effects of past pumping that have been propagating toward the reach for decades. Whether this is valid rationale is a policy question beyond the scope of this report, but use of steady-state modeling is consistent with the rationale.

Use of steady-state partitioning of responsibility would be logically consistent with steady-state calculation of curtailment date, as would the use of transient partitioning be consistent with transient calculation of curtailment. The linkages are a result of the concept that mitigation in lieu of curtailment is both defined and constrained by the alternate relief that curtailment would provide.

Time constraints preclude analysis using correct spatial distributions of irrigated lands and consumptive use, but the concept can be explored hypothetically. If each of the five points illustrated in Figure R3 represented an equal number of acre feet of consumptive use from groundwater, the assignment of responsibility could be made based on model-indicated contributions to the Near Blackfoot to Minidoka reach. Using the IDWR-generated steady-state models reflected in accompanying file "E2_SSRF.csv," the steady-state assignment to Row 27 Column 14 would be 1.8% of the total obligation. The four-month contribution of curtailment at that location is represented in Figure R9. Conversely, calculating percentages to three significant figures, the four-month transient contribution of curtailment at that location using ETRAN3.4 is 0.000%. This does not mean that there is *no* benefit, but that if mitigation in lieu of curtailment were to be defined and constrained by the accruals estimated per a transient curtailment, the technically-correct mitigation would be substantially less than the steady-state partition of responsibility.

It is my professional opinion that partitioning responsibility using a different modeling framework than was used to calculate curtailment can result in some users being held responsible for more mitigation than the relief that their curtailment would have provided.

Consistency between Precision and Burden

Conclusion of Law #21 articulates understanding of the fundamental difference between groundwater hydrology and surface-water hydrology, yet the unenviable burden of IDWR is to administer the connected resources conjunctively. To frame and provide context to the technical discussion of consistency between precision and burden, the following rhetorical questions are posed for surface-water Points of Diversion:

EXHIBIT "500"
Page No. 22 of 33

- Would prior appropriation require curtailment of junior whose Point of Diversion was adjacent to the senior Point of Diversion, given that curtailment of the junior could make water immediately available to the senior?
- Would prior appropriation require curtailment of a junior whose Point of Diversion was on a stream not tributary to the senior's source?

In essence, there is a continuum comprised of the ratio between the relief afforded the senior and the cost to the junior. In a surface-water context, results tend to fall on one end of the continuum or the other. In the first hypothetical, the ratio of benefit to burden is one to one. In the second, it is zero.

Some groundwater scenarios fall on the "zero" end of the spectrum; curtailment of a well in Rathdrum likely would not provide relief to the Surface Water Coalition. A few fall close to the "full and immediate relief" end of the spectrum; for instance, modeling indicates that curtailment at the location represented by Figure R11 would produce 35% accrual to Near Blackfoot to Minidoka within four months, and 45% within eight months.

The legal meaning of the Conclusions of Law #4, #5 and #6 is beyond the scope of this report but a plain-language reading suggests that priority is not the only factor to consider. The Rathdrum example indicates that a continuum exists for groundwater, as it does for surface water. Conclusion of Law #7 indicates that IDWR requires knowledge of *"how, when, where and to what extent the diversion and use of water from one source impacts the water flows in... other sources"* (emphasis added). If knowledge of something is required, the implication is that the knowledge must be utilized in making some decision. Under that assumption, *where* the cutoff is located is a policy decision, and once the decision is made, technical work can quantify where efforts fall in relation to it.

Conclusion of Law #21 states:

> *"Rule 43 of the CM Rules mandates that when the Director evaluates a mitigation plan, the mitigation plan must ensure that water is delivered to holders of senior priority surface water rights in both the quantity and at the time and place required by the senior. In considering a proposed mitigation plan pursuant to Rule 43, the Director must evaluate:*
>
> > ***b.*** *Whether the mitigation plan will provide replacement water, at the time and place required by the senior-priority water right, sufficient to offset the depletive effect of ground water withdrawal on the water available in the surface or ground water source at such time and place as necessary to satisfy the rights of diversion from the surface or ground water source. Consideration will be given to the history and seasonal availability of water for diversion so as not to require replacement water at times when the surface right historically has not received a full supply, such as during annual low-flow periods and extended drought periods.*
> > ***c.*** *Whether the mitigation plan provides replacement water supplies or other appropriate compensation to the senior-priority water right when needed during*

EXHIBIT "500"
Page No. 23 of 33

> *a time of shortage even if the effect of pumping is spread over many years and will continue for years after pumping is curtailed. A mitigation plan may allow for multi-season accounting of ground water withdrawals and provide for replacement water to take advantage of variability in seasonal water supply. The mitigation plan must include contingency provisions to assure protection of the senior-priority right in the event the mitigation water source becomes unavailable* (emphasis in Fifth Order).

Time constraints, the scope of this report and the expertise of the author preclude full exploration of the implications of this excerpt, in context of the full Conjunctive Management rules. The importance here is the explicit recognition of fundamental difference between time frames of surface-water processes and the effects of groundwater activities upon surface-water processes.

Within the context of both the magnitude of expected relief and the requirement that relief be timely, an added complexity of groundwater is that the linkages are not always apparent, nor are the methods to discern them infallible. An additional policy decision that could be articulated would be a specification of if or how precision of the knowledge of the degree of hydrologic connection might inform the policy decision of where the cutoff point is on the continuum between ratios of zero and one-to-one. If that decision were to be undertaken, it could be informed by technical knowledge of the precision of the model. IDWR's contribution to the 2012 white paper discussed above could be a starting point for analysis of the precision of the model, and such analyses may already have been performed. Qualitative insight into the relative quality of the model can be gleaned from comparisons of successive models, each in their time deemed to be the best available science.

Figure R17 shows a map of points that were used for such a qualitative view of ESPAM2.0, with graphical output provided in Figure R18. Figure R18 attempts to inform both quantity and timing issues. The top three panels, with blue-colored bars, show the fraction of accruals from the three points that the models indicate would be captured by a particular reach. The bottom panels, with red-colored bars, represent the differences in modeled timing of accrual. The metric is the number of months for the model to indicate that half of the captured accruals have arrived at the reach of interest.

EXHIBIT "500"
Page No. 24 of 33

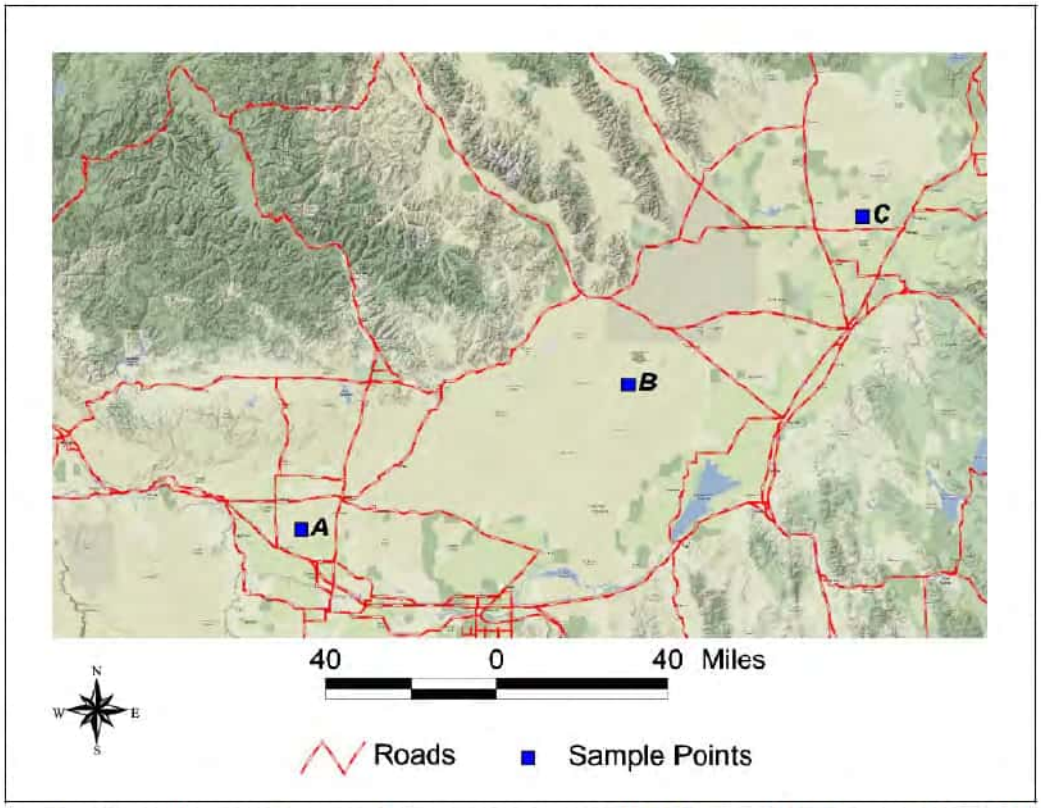

Figure 7. Sample points used to compare SRPAM, ESPAM1.1 and ESPAM2.0.

Figure R17: Figure 7 reproduced from Technical Report on ESPAM2.0 Modeling Issues

EXHIBIT "500"
Page No. 25 of 33

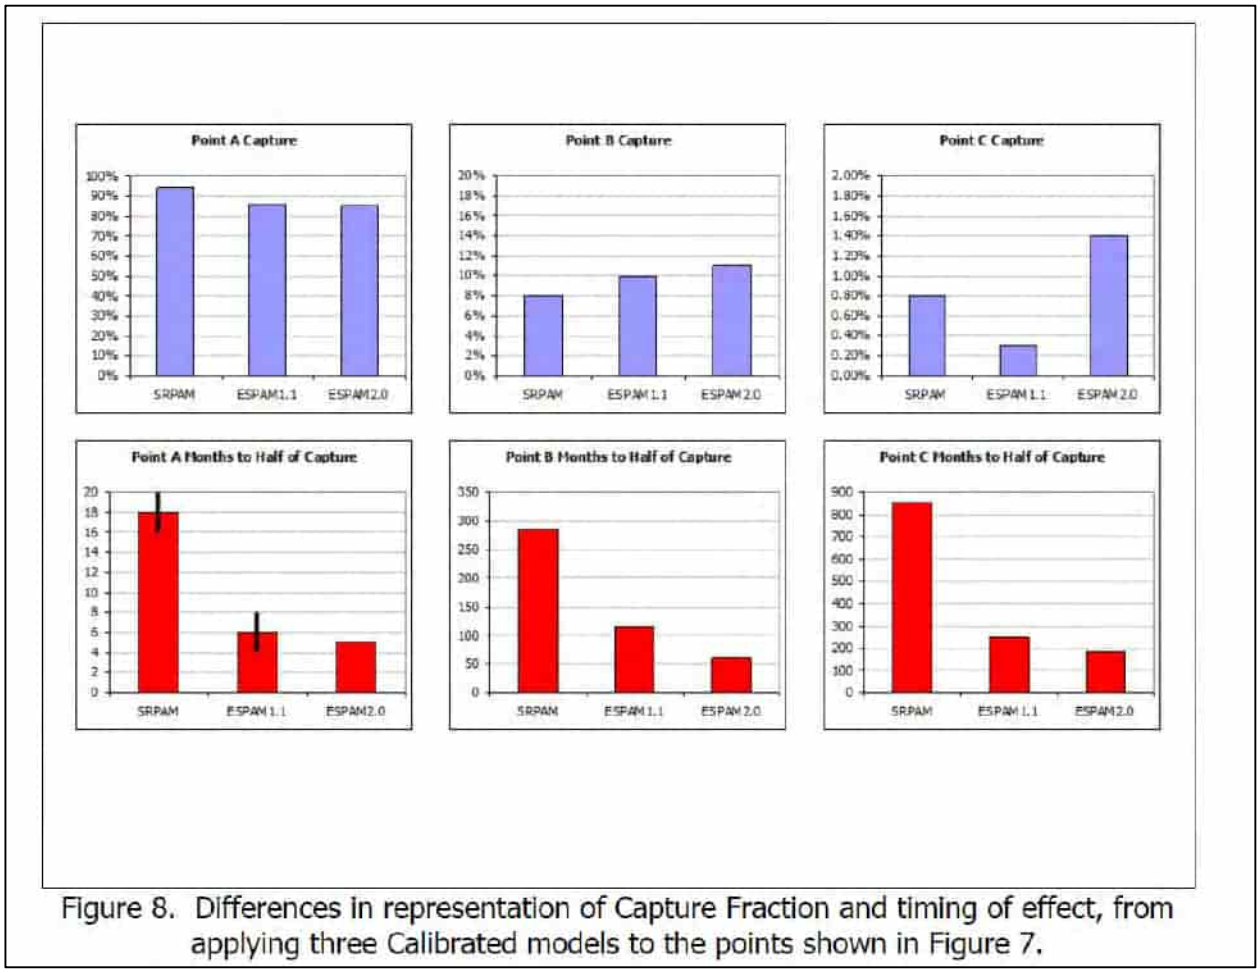

Figure 8. Differences in representation of Capture Fraction and timing of effect, from applying three Calibrated models to the points shown in Figure 7.

Figure R18: Figure 8 reproduced from Technical Report on ESPAM2.0 Modeling Issues.

Time constraints preclude comparison of ESPAM2.0 with ESPAM2.1, but Figure R19, Figure R20 and Figure R21 allow qualitative assessment of the differences between ESPAM2.1 as realized in the ETRAN3.3 Transfer Tool, and ESPAM2.2 as realized in the ETRAN3.4 transfer tool. Table R3 summarizes qualitative comparisons of the two models for these three points. The points intentionally are of disparate character and are not intended to be representative of the plain as a whole.

Table R3. Qualitative Comparison of ESPAM2.1 and ESPAM2.2 via Figures R19, R20 and R21

Point	General Location	ESPAM2.1 Years to Peak	ESPAM2.2 Years to Peak	Subjective Comparison of 10-year Sum of Accruals
R75 C57	A&B Irrigation District	1.67	3.67	ESPAM2.1 slightly higher
R83 C123	Very close to Near Blackfoot to Neeley	0.33	0.33	Very similar
R50 C191	Near Henry's Fork	5.00	6.67	Very similar

EXHIBIT "500"
Page No. 26 of 33

001917

These results underscore Eastern Idaho Water Right Coalition's 2012 observation that:

> All of these uncertainties are a function of the spatial scale at which answers are sought. If the question is asked: "How much pumping at location X will propagate to river and spring reaches?" the answer can be determined with very little uncertainty, and independently of the limitations described above.
>
> If refined estimates of above-Milner vs. below-Milner effects are required, the uncertainty depends on the location of the well. For wells distant from Milner, none of these conceptual simplifications are likely to materially affect the answer. For wells near to Milner, all of these affect the results and a different set of assumptions would be expected to produce a markedly different result.
>
> Similarly, refining the question to include some understanding of the timing of effect begins to introduce additional uncertainty. The answer to "How much will propagate in time period Y" is less certain than "How much will eventually propagate," and results are sensitive to changes in conceptual simplifications.

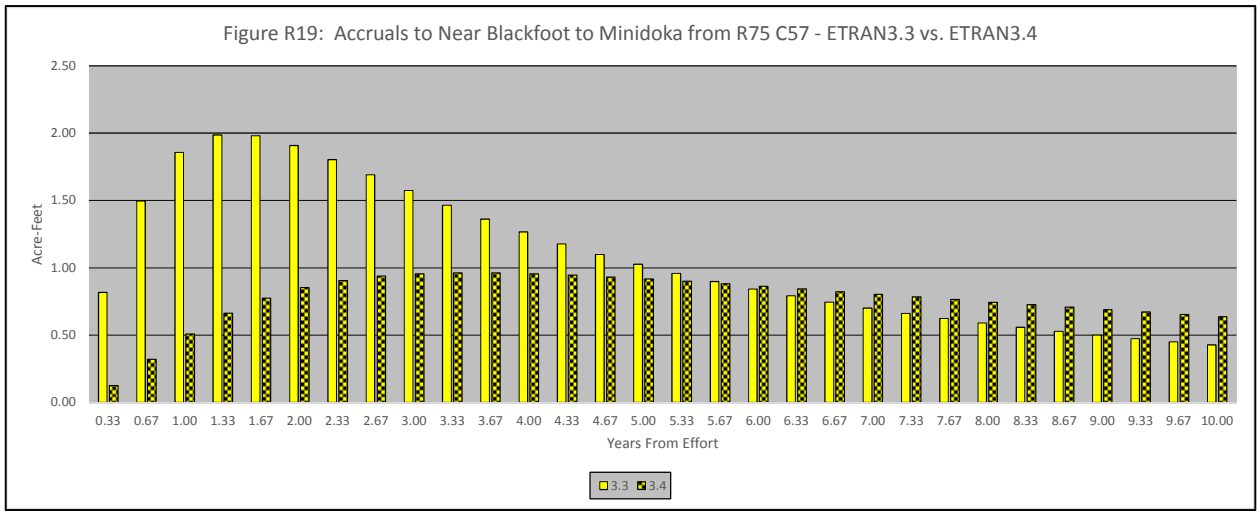

Figure R19.

EXHIBIT "500"
Page No. 27 of 33

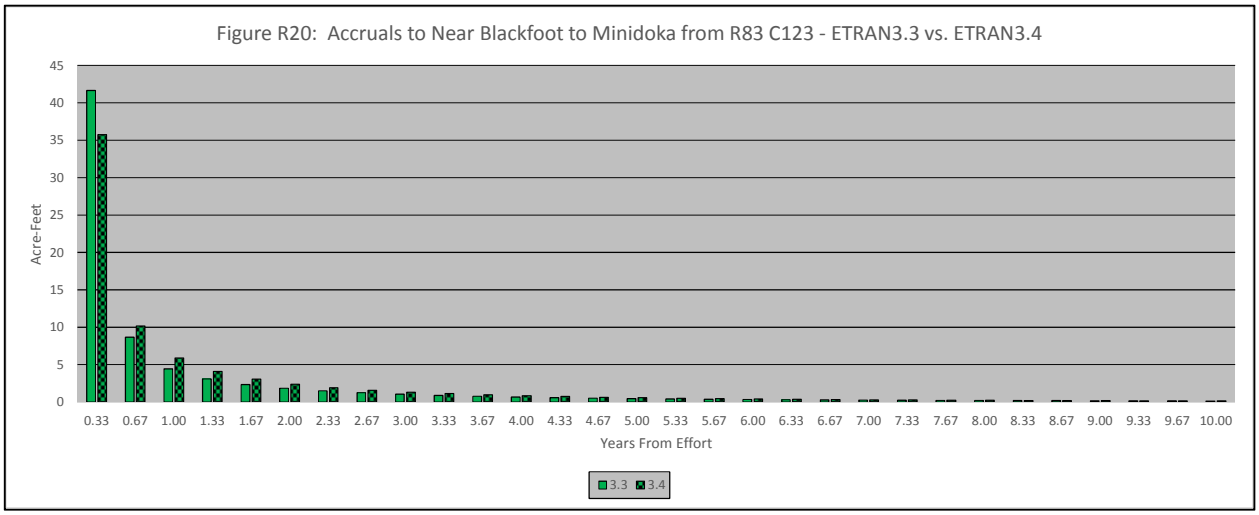

Figure R20.

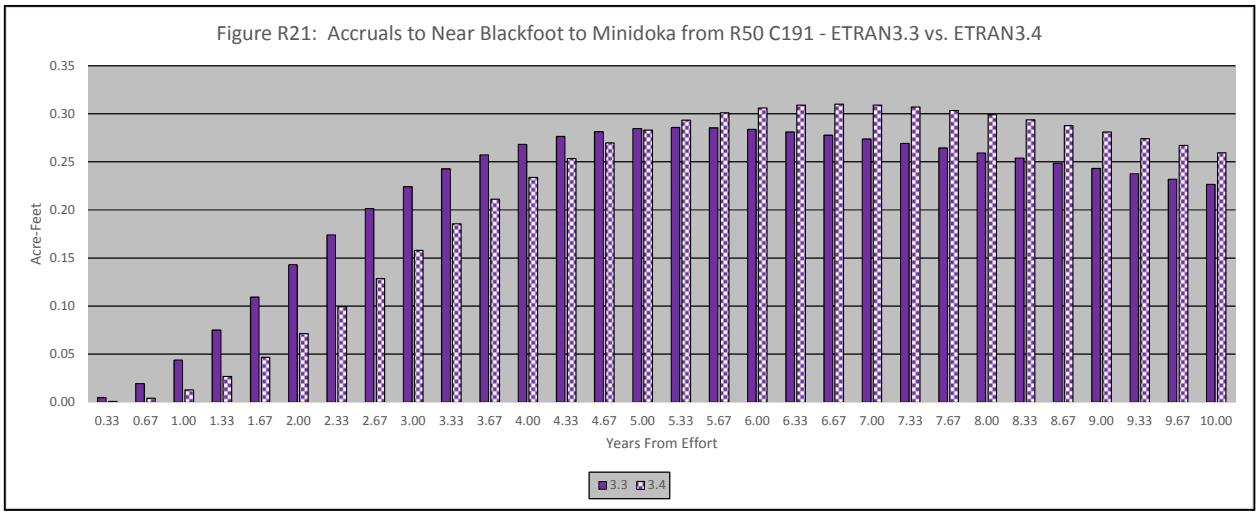

Figure R21.

A thoughtful reader might ask a policy question such as: "Is it fair to the SWC to use the model to estimate timing of accruals in the trimester of curtailment, when the two most recent best-available-science models differ by approximately a factor of six?" Technical analysis could inform policy deliberations about such a question.

Discussion of Technically-consistent Options

As indicated earlier, this report attempts to remedy a shortcoming identified by the hearing officer in another case, that expert reports offer no solutions. While implementation of a solution is a policy decision, technical work can help frame the understanding of what is possible, and what the implications of alternatives might be.

EXHIBIT "500"
Page No. 28 of 33

Alignment of Modeling Time Frame with Policy. In deposition in May 2023, Jennifer Sukow stated that she was *"told by Allan Wylie that [former Director] Karl Dreher did not want to use a transient analysis, because he did not like the additional volume of water that would accrue to the reach in future years."* This may have been how the decision was communicated, but it is likely that rather than not "liking" the result, the former Director deliberately selected steady-state analysis as a policy response to some of the temporal issues that have been explored above. However, applying the steady-state values only in years of shortfall still was technically inconsistent with the temporal delay in accrual. The Fifth Order methodology attempts to address that inconsistency but brings others, discussed above. The current methodology produces results such as seen in 2023, with curtailment of most groundwater irrigation threatened in a season of abundant snowpack and local flooding in some areas.

Visual inspection of Figure R16 suggests a cyclical pattern with a period of a few years. Robust time series analysis likely could quantify the periodicity. The periodicity likely could be partitioned into components of different periodicity, such as natural flow, return flows from surface-water irrigation, and groundwater contribution. Both time-series analysis and water-budget analysis could contribute to this understanding. Additionally, if the zeros in the hindcast were replaced by numerical values of surpluses that occurred, a statistical distribution of supply could be derived that would allow calculation of an appropriate level of conservatism to protect the SWC interests.

Similarly, as shown by Figures R8 through R13 and R19 through R20, the transient ESPAM model could be used to explore the characteristic time of response for curtailment of zones of similar hydraulic distance from the reach in question.

Combined, these two analyses could inform a curtailment scheme and a frequency of adaptive management that allowed the temporal pattern of need to be matched to the temporal response of reach gains to curtailment activities.

It is my professional opinion that a technically- and logically-coherent curtailment strategy could be constructed using either steady-state or transient analysis. The key would be to align the calculation and expectations of relief to the physical time frame of aquifer response. Something akin to Sukow's proposal for considering future accruals likely would be an important element.

Accounting for Non-Target Accruals. The key to accounting for non-target accruals is to be sure that the accounting decay of accruals, and the spatial assignment, match reality. A possible method is described in the Journal of the American Water Resources Association (Contor, 2009) that links transient *"aquifer response functions with double-entry accounting technologies"* and *"honors the hydrologic realities of groundwater/surface water interaction, the legal requirements of prior appropriation water law, and the economic requirements for equitable and efficient allocation of resources."*

EXHIBIT "500"
Page No. 29 of 33

Summary and Conclusions

My professional opinions regarding the Fifth Order are as follows:

- The arguments presented for transition to transient modeling are not factually correct, and therefore the true rationale has not been revealed.
    - Because I do not have access to the true rationale, I cannot assess it technically.
- Unless the criteria for accuracy and precision are very low, ESPAM2.2 is not sufficiently precise for monthly estimation of effects to the Near Blackfoot to Minidoka reach, for decisions that precipitate large financial burdens.
- The use of ESPAM modeling is technically defensible when ratios of relief to cost are considered in light of modeling precision, and when policy adjusts for spatial and temporal differences in response.
- The arguments presented against considering supplemental groundwater use within the SWC are not factually correct, and therefore I cannot technically assess the unrevealed true rationale.
- It is technically possible and reasonably achievable to assess and address supplemental groundwater use within the SWC.
- The following factors multiply the effect of ignoring supplemental groundwater use within the SWC:
    - Because of inherent characteristics of surface-water delivery systems, supplying one acre with surface water requires substantially more water than supplying an acre with groundwater.
    - Not all effects of curtailment of groundwater propagate to the Near Blackfoot to Minidoka reach, so more than one acre foot of curtailment is required to produce one acre foot of accrual.
    - When obligations are calculated on a transient basis, the temporal delay in propagation creates an additional multiplier of effort.
- Partitioning responsibility using a different modeling framework than was used to calculate curtailment can result in some users being held responsible for more mitigation than the relief that their curtailment would have provided.
- Technical methods exist to inform a coherent plan under either a transient or a steady-state paradigm.

SNAKE RIVER PLAIN AQUIFER MODEL SCENARIO:

HYDROLOGIC EFFECTS OF CURTAILMENT OF GROUND-WATER PUMPING USING SNAKE RIVER PLAIN AQUIFER MODEL VERSION 1.1

"Curtailment Scenario"

INTRODUCTION

Hydrologic Effects of Curtailment of Ground-Water Pumping (also known as the Curtailment Scenario), was originally performed using version 1.0 of the Snake River Plain aquifer model [Idaho Water Resources Research Institute (IWRRI), 2004]. The Eastern Snake River Plain Aquifer Model (ESPAM) has been updated to version 1.1, and the results of re-running the Curtailment Scenario with the updated model are presented here. The Curtailment Scenario is one of many Snake River Plain aquifer model scenarios being developed to assist in resolution of conflicts among water users and guide future water management such as implementation of managed recharge. Water management should be guided by a collective perspective from many of the scenario evaluations rather than a single document.

The present version of the ESPAM was developed with funding provided by the State of Idaho, Idaho Power Company, the U.S. Geological Survey, and the U.S. Bureau of Reclamation. The model was designed with the intent of evaluating the effects of land and water use on the exchange of water between the Snake River Plain aquifer and the Snake River. This evaluation is part of the application of the model towards this purpose.

The model was developed by the IWRRI under the guidance, and with the participation of, the Eastern Snake Hydrologic Modeling Committee (ESHMC). The effort was led by the Idaho Department of Water Resources (IDWR) and active participants in the Committee included Idaho Power Company, the U.S. Geological Survey, the U.S. Bureau of Reclamation, IWRRI and technical experts representing water user groups. The ESHMC has also served to guide and review the scenario evaluation process. Documentation of the model and related activities are available from the IDWR and the IWRRI at the University of Idaho.

This "Curtailment Scenario" is intended to answer the question "If all ground-water rights with priorities after a specified date were to be curtailed, what would the effect be on spring discharge and Snake River gains and losses?" This set of scenario simulations assesses this question for ground-water rights with priorities junior to the following dates:

a) the onset of ground-water irrigation (1870)
b) January 1, 1949
c) January 1, 1961
d) January 1, 1973
e) January 1, 1985

The underlying theory of this set of scenario simulations is that if all ground-water rights junior to a certain priority date were to be curtailed, benefits would be accrued to the river gains and spring discharges from the eastern Snake River Plain aquifer. These simulations illustrate the model-predicted increases in river gains and spring discharges over time. Benefit to river gains could be in the form of increased aquifer discharge to the river, decreased losses from the river to the aquifer or increased spring discharge from the aquifer. Future reference to increased river reach gains in this report will include all three of these cases.

It is important to recognize that even after curtailment of ground-water rights, there is a residual impact to river reaches due to previous years of ground-water pumping. The magnitude and timing of this residual impact can also be evaluated using these scenario simulations.

The Curtailment Scenario has been evaluated using numerical superposition. Using numerical superposition, the impacts of curtailment of ground-water pumping can be assessed in isolation of all other recharge and discharge.

The purpose of these scenario simulations is to determine and describe how spring discharges and river gains and losses would be affected by curtailment of ground-water pumping with priorities junior to some specified date. The specific objectives are to:

1) Determine the magnitude of increase in spring discharges and river gains over time for each sub-reach of the Snake River.
2) Determine the seasonal magnitude of the expected increases.
3) Determine the predicted impacts to aquifer water levels.

A related report exists which documents the Modflow files used for the Curtailment Scenario. This report is: Addendum A: CURTAILMENT SCENARIO: Modflow DATA AND PROGRAMS (DDS-004rev1–Addendum).

ESPAM Version 1.1

In May 2005, errors were discovered in v1.0 of the calibrated ESPAM, necessitating recalibration of the model. Correction of these errors and recalibration resulted in ESPAM v1.1, as documented in the ESPAM project final report. Most notable among the errors were: a) ESPAM v1.0 was inadvertently calibrated using the old irrigation return flow lag factors, and b) there was a discretization error in the Shelley to Near Blackfoot and Near Blackfoot to Neeley reaches. Each of these errors would cause a re-distribution of recharge and discharge among reaches of the Snake River and affect the final model parameters (transmissivity, storativity and riverbed conductance). The ESHMC decided that the Curtailment Scenario should be re-run using ESPAM v1.1.

BACKGROUND

Since the onset of ground-water irrigation on the eastern Snake River Plain, ground-water withdrawals have impacted aquifer water levels and river gains and losses. Initially, ground-water pumping removes water from aquifer storage, causing a localized cone of depression. As pumping continues, the effects propagate until a hydraulically connected boundary is reached. A recharge boundary will act as a source for the water being removed via ground-water pumping. Changes in aquifer water levels will impact the amount of water being recharged or discharged from a hydraulically connected recharge or discharge boundary. For example, in a hydraulically connected river reach, the relationship between river stage and aquifer water level will determine the amount of

water moving between the aquifer and the river. For a gaining river reach, a decrease in aquifer water level will result in a decrease in the rate of ground-water discharge to the river.

Sources of recharge and discharge on the eastern Snake River Plain include precipitation, recharge incidental to surface water irrigation, ground-water withdrawals, evapotranspiration, tributary valley underflow, and river gains and losses. Of these sources of recharge and discharge, only the Snake River gains and losses are modeled as head-dependent.

As time passes and the collective impacts of ground-water pumping on the eastern Snake River Plain propagate throughout the aquifer system, less of the removed water is coming out of aquifer storage and more is coming from the river, either in the form of reduced spring discharges, decreased aquifer discharges to the river, or increased losses from the river. Ultimately, however, all of the ground water pumped and consumptively used for irrigation will come from the Snake River. It is difficult to quantify the volume and timing of these impacts to the river reaches. A numerical ground-water model is the best available tool for such an estimation.

Historically, the development of ground-water irrigation lagged the development of surface water irrigation by several decades. Figure 1 shows the increase in nominal diversion rate of ground-water rights versus time. The development of ground-water-irrigated land was tied to rural electrification and innovations in pump technology. This increase in ground-water development and other changes in water use caused a corresponding trend of decrease in river gains over time. The resultant decrease in surface water supplies has the potential for a senior surface water user to be damaged by a junior ground-water user. This is the motivation for investigating the potential hydrologic changes associated with curtailment of ground-water use by priority date. In presenting these scenario results, no implication is made of injury to surface water users. The results presented in this paper merely illustrate the potential impact to river gains and losses which could be attained via curtailment.

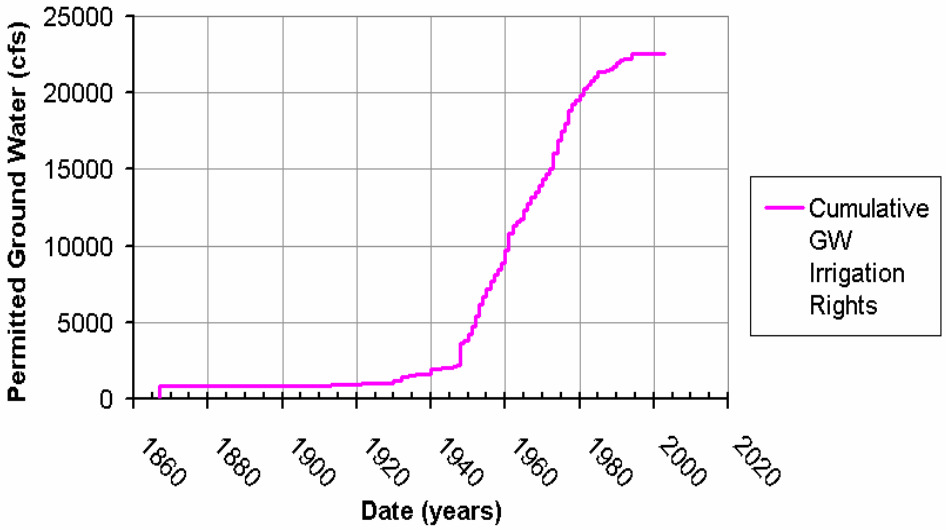

Figure 1. Ground water priorities on the eastern Snake River Plain.

DESCRIPTION OF THE NUMERICAL SUPERPOSITION MODEL

The numerical superposition version of the ESPA model is very similar to the fully populated ESPA model with all recharge and discharge terms removed and with a zero initial gradient. The numerical superposition model uses the concepts of superposition as detailed in Reilly and others (1987). The fundamental basis of superposition theory is that, for a strictly linear system, a complex problem can be decomposed into more simple sub-problems. The sum of the solutions of the sub-problems will be the same as the solution to the whole, more complex problem.

The ESPA model is a confined representation of a generally unconfined aquifer system. Confined aquifer model representations are strictly linear; unconfined aquifer model representations are non-linear due to the fact that aquifer transmissivity changes as aquifer water levels change. In the eastern Snake River Plain aquifer, the changes in water levels are very small relative to the total saturated thickness, so these non-linearities are considered negligible. A comparison of the confined version of the ESPA model versus the unconfined version has been done by IWRRI and is published in ESPAM Design Document DDM-019, Comparison of Unconfined and Confined Aquifer Representation. Similarly, a comparison of model results using the fully populated model versus the numerical superposition model has been done by IWRRI and will also be documented in a report. The results of these evaluations support the conclusion that the non-linearities of the ESPAM are negligible. These results have been presented to the ESHMC.

Model parameters, which represent physical traits of the aquifer system, are the same for the numerical superposition model and the fully populated model. These parameters include aquifer transmissivity and storativity and river and drain conductance. The

numerical superposition model requires a zero initial hydraulic gradient, so the initial aquifer head is uniformly set to zero. The Modflow (McDonald and Harbaugh, 1988) representation of drains (springs) only allows water to leave the aquifer. The Modflow representation of rivers allows water to leave or enter the aquifer. Otherwise, drain and river representations in Modflow are identical. For the numerical superposition model, all drain cells (which were used to represent spring discharge between Milner and King Hill) are converted to river cells. The initial elevation of the river cells is set to zero. This creates an initial condition where there is no flux between the aquifer and surface water features. All recharge and discharge terms are removed in the numerical superposition model except for the aquifer stress being evaluated. For example, simulation of an aquifer stress will induce flux from represented surface water features in an amount that is equal to the depletion of rivers and springs for the same stress in the fully populated model. The results from this simulation represent the impacts from the particular aquifer stress being evaluated in isolation of all other recharge and discharge.

A simple example of an evaluation using numerical superposition would be an evaluation of the impacts to river reaches due to pumping at a single well. Pumping at the well does not affect any of the sources of recharge or discharge which are not hydraulically connected. For example, pumping will have no effect on precipitation or evapotranspiration from shallow-rooted plants in an area where the water table is deep, such as in the eastern Snake River Plain aquifer. The cone of depression from the pumping well will propagate radially from the well until the resultant drawdown affects water levels near a river reach. At that time, the pumping will result in a reduction of the river gain or increase in river loss. By analyzing this stress using the numerical superposition model, all exchanges between the river and aquifer will be due to the ground-water pumping being evaluated. Evaluation of the same pumping well using the fully populated model would require running the fully populated model with and without the pumping well and differencing results of the two model runs. The latter analysis is more cumbersome and more prone to analysis and numerical error.

Evaluation of the impacts of curtailment of ground-water pumping was greatly facilitated by using the numerical superposition model. The numerical superposition model is not restricted to the 22-year period of the fully populated model and the effects of curtailment can be evaluated in isolation of all other recharge and discharge, yielding an estimate of expected *changes* in river gains and spring discharges due to curtailment. Evaluations of the results of these scenarios using numerical superposition can be used to estimate expected future impacts to river gains due to curtailment and the residual impacts to river gains from ground-water pumping after ground-water curtailment. Using superposition allows analysis of the future impacts of a specified stress (in this case, ground-water pumping) without requiring knowledge of other future conditions such as weather.

GROUND-WATER PUMPING CURTAILMENT ANALYSIS METHOD

The Curtailment Scenario has been evaluated using the following general steps:

a) Retrieve data from the IDWR water rights database which describes point of diversion, purpose of use, priority date, diversion rate and place of use for all ground-water rights. The results of this one-time query were intersected with the model grid and stored in a database.
b) Query the database created in step a) for ground-water irrigation rights with a priority date junior to the date of interest. The percentage of ground-water use in each model cell that is junior to the specified priority date is calculated. The results are applied to the current GIS layer of irrigated lands and multiplied by the ground-water irrigated area within the model cell, creating a new GIS layer containing the lands irrigated under water rights that are junior to a specific priority date.
c) Apply average (1961-1990) values of precipitation and average (1980-2001) evapotranspiration to this new irrigated lands coverage to estimate net consumptive use for the lands identified in the query. For the long-term curtailment assessment, the annual averages of precipitation and evapotranspiration were used. For the seasonal curtailment assessment, summer and winter (corresponding to irrigation season and non-irrigation season) averages were used. These data were used as input to the GIS-Fortran Recharge Program to create the Modflow Well File for the numerical superposition version of the ESPA ground-water model, representing only the consumptive use associated with ground-water development across the eastern Snake River Plain under water rights that are junior to the specified priority date.
d) Run the numerical superposition version of the ESPA ground-water model using the Modflow Well File created in step c). Both the steady state and transient numerical superposition versions of the ESPA ground-water model were run for this step.
e) Determine the impacts to each river reach due to the ground-water pumping.

Step a) was only done one time. Steps b) through e) were done once for each of the five selected priority dates and for both the average and seasonal cases. Each of these steps is described in more detail in Appendix A.

For the ESPAM v1.1 version of the Curtailment Scenario, no changes were made to the GIS processing used to produce the Modflow well file. Therefore, the only changes were to the Modflow files representing storativity, transmissivity and river and drain conductance.

DISTRIBUTION OF CURTAILED AREAS

How river reaches are affected over time by curtailment depends on the distribution of the area being curtailed and the consumptive use associated with the curtailed area. Figure 2 shows the proportion of the ground-water irrigated area junior to 1870 (nearly all ground-water irrigated lands) for each model cell. The irrigated areas are color-coded, with dark cells being 80-100% irrigated by ground water junior to 1870, lighter colors being less. Figures 3 through 6 show the proportion junior to January 1, 1949, January 1, 1961, January 1, 1973 and January 1, 1985, respectively. Figures 2 through 6 show the

spatial distribution of ground-water use relative to river and spring reaches as well as the location of new ground-water development for each time period.

Close inspection of Figures 2 through 6 shows where ground-water development was most common during various time periods. For example, looking at the difference between Figures 3 and 4, it is clear that much of the development with priority dates between 1949 and 1961 was in the area of the A&B Irrigation District, the Oakley Fan and north of American Falls.

The analysis of curtailed areas excluded ground-water rights in the Ft. Hall area that were senior to 1870. These are tribal rights and are not subject to curtailment. Appendix B contains a summary of the number of curtailed acres and the associated amount of consumptive use by ground-water district.

MODELING ANALYSES

Determine the Magnitude of Expected Spring and River Accruals Due to Long-Term Curtailment of Ground-Water Pumping (Objective 1)

Curtailment of ground-water pumping will result in increases in river gains (or decreases in river losses) either due to a) increased spring discharge in the Thousand Springs and American Falls area or b) higher aquifer water levels near other hydraulically connected reaches of the river, causing more water to discharge to the river reach (or, in the case of a losing reach, causing less water to be lost from the river reach). River gains were evaluated for each of the five cutoff dates for ground-water pumping as detailed in the Introduction. The gains were evaluated for both the steady state case (infinitely long time) and for the transient case (predicting impacts over time).

Steady State Results

Steady state simulations were performed to predict the accruals to river reaches after the full impact of the curtailment has been realized. The steady state analysis presumes the unlikely case that pumping has been permanently curtailed. Table 1 lists the predicted steady state gains by river reach for each modeled cutoff period. Additionally, Table 1 lists the time for each reach to come within 10% of the steady state value. For example, in Table 1, curtailment of all ground water is predicted to cause a 298 cfs accrual in the Devil's Washbowl to Buhl reach. Transient simulation results indicate that it would take approximately 59 years for the recovery to reach 90% of the steady state value. Similarly, curtailment of ground water junior to January 1, 1973 is predicted to cause an 88 cfs recovery in the same reach. Ninety percent of this recovery would be realized in 51 years.

Comparison of Table 1 with Figures 2 through 6 shows that the magnitude of the predicted accrual for each reach is dependent upon proximity of the area being curtailed to the specific reach and the volume of ground water pumped within that area. For example, although the Devil's Washbowl to Buhl reach has significantly less spring

discharge than the Malad reach, the predicted steady state gain in the Devil's Washbowl to Buhl reach due to curtailment of all ground-water pumping is 298 cfs versus 77 cfs for the Malad reach. Figure 2 shows that most of the ground-water irrigated acres are east of the Malad reach, so curtailment will have the greatest impact in the eastern and northern areas of the eastern Snake River plain. Table 1 provides some indication of the spatial distribution of predicted impacts due to curtailment of ground-water irrigation.

Transient Results

Figures 7 through 17 show the predicted reach accruals over a long period of time for each modeled reach, for each cutoff date. For example, Figure 17 shows predicted accruals for the Malad to Bancroft reach in the Thousand Springs area. The yellow line in Figure 17 represents the expected reach accrual (which, in this case, equates to an expected increase in spring discharge for this reach) if ground-water pumping junior to January 1, 1985 were to be curtailed. Similarly, the orange line shows expected accruals if pumping junior to January 1, 1973 were curtailed, etc. Each figure also shows the steady state value for predicted accruals for each of the cutoff dates.

Also apparent in Figures 7 through 17 is the fact that some of the river reaches approach steady state more rapidly than others. This is due to how proximal the curtailed ground-water pumping is to the river reach and the magnitude of the change in stress. If the pumping is distant from the reach or the change in stress is very large, the effects take longer to propagate through the aquifer, causing a longer time until steady state is reached.

Similarly, within a given reach, curtailment related to each cutoff date approaches steady state at a different rate. Again, using Figure 17 as an example, in the Malad to Bancroft reach, the impacts associated with a cutoff date of January 1, 1985 approach steady state after approximately 50 years. However, the impacts associated with a cutoff date of January 1, 1949 do not approach steady state until approximately 90 years. This is due to the spatial distribution of the ground-water pumping being curtailed as well as the spatial distribution of storativity and transmissivity. The response to curtailment will also vary reach by reach. Figures 7 through 17 were generated using an average annual net consumptive use and, therefore, show no seasonality.

Table 2 summarizes the predicted reach accrual after one year of curtailment for each reach for each cutoff date. These results can be used to estimate impacts of curtailment of ground-water pumping on a year-by-year basis. Looking at the Buhl to Thousand Springs reach, a 1-year curtailment of all ground-water pumping junior to January 1, 1870 would result in a 34,000 acre-foot accrual. Similarly, in the Buhl to Thousand Springs reach, a 1-year curtailment of all ground water junior to January 1, 1973 would result in a 16,000 acre-foot accrual by the end of that year.

Determine the Seasonality of River Accruals Due to Curtailment of Ground-Water Pumping (Objective 2)

The seasonal nature of ground-water pumping will cause the impacts of curtailment to have seasonal swings. These seasonal swings will be most prominent in reaches very close to curtailed areas and more dampened in reaches that are affected more by distant ground-water pumping. The seasonal swings are important, however, in that the reach accruals due to curtailment will vary seasonally and not be a continuous smooth curve as those shown in Figures 7 through 17. This means that the peak of the accrual due to curtailment may come at a time other than when the water is most needed in the reach.

Since curtailment represents the cessation of an activity, it is conceptually difficult to understand why the predicted accruals will have a seasonal component. These simulations are intended to predict the changes in river reach accruals due to curtailment. Under normal operation, the river reaches would be seasonally impacted due to ground-water pumping, with depletions occurring during the irrigation season and recovery during the non-irrigation season. The numerical superposition model is used for estimating *changes* in river reach gains. When these changes are superimposed on measured reach gains, the model predicts what the measured reach gains would have been, had the change already occurred. Figures 18 through 28 show curtailment effects during the irrigation season with an estimated attendant reach accrual, and less accrual during the non-irrigation season because there is no pumping to curtail at that time.

Figures 18 through 28 show the seasonal predictions of reach accruals for the 11 reaches of the Snake River for each of the five cutoff priority dates. Each of these figures shows the characteristic increase in reach accruals during the irrigation season with a diminished accrual during the non-irrigation season. The reader should note that the scale on the y-axis varies for each of the graphs in Figures 18 through 28, indicating a variation in magnitude of the accrual and the seasonal variation. The magnitude of the seasonal variation depends upon how close the reach is to the areas being curtailed and the overall magnitude of the predicted reach accruals. For example, the Malad-Bancroft reach, shown in Figure 28, has a seasonal variation in spring discharge of only about 3 cfs due to curtailment of all ground-water pumping. In contrast, the Buhl to Thousand Springs reach, shown in Figure 24, has an almost 80 cfs seasonal swing between spring and fall.

Many of the reaches depicted in Figures 18 through 28 show a winter decline almost back to the river reach gain levels of the previous year. Some of the reaches, however, show a smaller decline relative to the predicted accruals. This would indicate that the curtailed areas are more distant from the reach and that the accruals are taking longer to get to the reach. Figure 18 shows this dampened seasonal effect for the Ashton to Rexburg reach. Inspection of Figures 2 through 6 show that relatively little of the curtailed area is close to this reach, so the impacts are traveling further and are attenuated before impacting the Ashton to Rexburg reach.

Figures 18 through 28 also show the predicted 10-year accrual for a 1-year curtailment of pumping junior to 1985 and pumping junior to 1870, for each reach. As can be seen in

Figures 18 through 28, even after the 1-year curtailment is lifted, there would be residual accruals at the river reach from the 1-year curtailment.

Determine the Predicted Impacts to Aquifer Water Levels After Curtailment of Ground-Water Pumping (Objective 3)

Just as curtailment of ground-water pumping will cause increases in river gains, curtailment will also cause a recovery of aquifer water levels. Figures 29 through 34 show predicted changes in aquifer water levels at six locations throughout the plain due to curtailment of all ground-water pumping. In each case, the aquifer water levels are predicted to rise. The magnitude of the rise is driven by how proximal the curtailed ground-water irrigated lands are to the river reach under evaluation.

SUMMARY

Curtailment of ground-water pumping by specified priority date will have varied impacts on reaches of the Snake River, depending upon the location and size of the curtailed areas. Even with permanent curtailment of ground-water pumping, there would be residual impacts to the river for decades into the future. The magnitude of predicted accruals at each river reach is dependent upon how close the curtailed area is to each reach and the magnitude of the curtailment.

There will be a seasonal aspect to the actual accruals to river reaches as a result of curtailment. Curtailment will result in peak increases in the fall, at the end of the irrigation season, declining over winter to a low in the spring. This seasonal aspect to the recovery of the modeled reaches could be important depending upon what the water is being used for.

For the temporary, 1-year simulation, maximum realizable accruals are relatively small but the benefits last for several years. Most of the ground-water pumping occurs in the eastern and northern portions of the eastern Snake River plain, creating a natural limit on the benefit that can be realized at the most western reaches of the Snake River.

Appendix A. Detailed Procedures Used for Curtailment Scenario.

Data Retrieval from IDWR Water Rights Database

The point-of-diversion water right table described in the main body of the report is based on the IDWR water rights and adjudication databases, and processed specifically for this application. IDWR personnel extracted point-of-diversion data for all ground-water rights within all the Administrative Basins that intersect the plain. Because of the ongoing Snake River Basin Adjudication, each right may be represented in multiple locations within the databases. The query was structured to avoid duplicate retrievals and extract only current data. Where available, adjudication partial decrees were used.

The result was two data tables. The first was a point-of-diversion table that contained an entry for every unique combination of point of diversion and water right. The table contained many data fields, including geographic location (X and Y coordinates), a water-right identifier, a priority date and an enlargement flag. The second table was a water-right table that contained an entry for every unique combination of water right and water use. This table included the water-right identifier, water use, and diversion rate specific to the water use.

A GIS program was used to assign model-cell identifiers to each point of diversion, and perform a many-to-many data-table join. This generated a data table with an entry for every unique combination of point of diversion, water right, and water use. For each use, the associated diversion rate was apportioned to all points of diversion for that use, for that right. The priority dates were retained in calendar date format, but were also recorded in new data fields representing the priority dates as integer numbers. One of these represented the nominal water-right priority date and the other represented the effective date, considering that enlargement water rights are subordinated to April 12, 1994. IWRRI and IDWR performed careful quality-assurance checks on the joined data table (Ciscell, 2004).

Determination of Net Consumptive Use Associated With Ground-Water Irrigated Areas Junior to Specified Priority Date

Irrigated areas were identified using the GIS polygons used in model calibration. Water-right place-of-use descriptions were not used to determine irrigated areas because of the effects of overlapping water rights. Irrigation water source (i.e. surface water or ground water) was identified using data from the model calibration.

In the recharge tool, the irrigated area for each model cell was calculated using GIS-derived area multiplied by a source fraction. In these simulations, the source fraction was set to zero on surface-water-irrigated areas (including the surface-water member of each mixed-source pair). On ground-water-irrigated areas (including mixed-source members), the source fraction was set equal to the calibration-period source fraction (indicating the fraction of irrigation water supplied by surface or ground water) multiplied by a

consumptive use fraction. The consumptive use fraction was based on priority dates and derived from water right point-of-diversion data.

Scenario consumptive use was based on the average of 22 years of calibration data (May, 1980-April, 2001). In the recharge calculations, consumptive use is applied only to irrigated areas. By scaling the irrigated area according to priority-date consumptive fraction, only the consumptive use represented by the selected priorities was applied to the model.

The consumptive use associated with a given priority date was determined by the fraction of total diversion rate that is junior to the given priority for water-right points of diversion within each model cell. Face-value diversion rates were used, without considering combined use limitations, because only the face-value rate is readily extracted by a database query. This process of scaling the calibration-data consumptive use allows direct comparison to other model runs and avoids the difficult problem of establishing a linkage between water-right diversion rate and consumptive use. It relies on an assumption that the progression of nominal diversion rate over time paralleled the progression of consumptive use.

To test this key assumption, a statistical sampling of 20 quarter-quarter sections was evaluated. All irrigation rights within each tract were examined manually, considering all combined use limitations on acreage. The actual progression of irrigated acreage over time was calculated, assuming that consumptive use would correspond to irrigated acreage. This was compared with the progression of nominal diversion rate that could be automatically extracted from the data. Some individual tracts showed considerable over- or under-estimation at some priority dates. Figure A-1 shows the combined results for the entire sample. Across the range of priority dates, the difference between the two methods was not statistically significant.

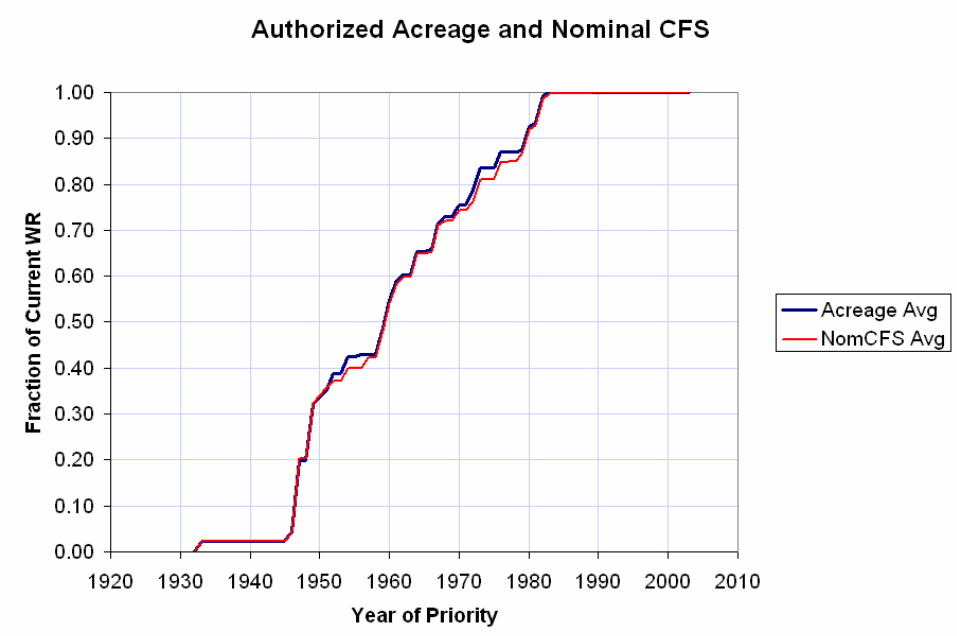

EXHIBIT "502"
Page No. 14 of 23

Figure A-1. Results of diversion-rate method test for statistical sample

To move from a data table of diversion rates to a consumptive use fraction by model cell, a Visual Basic program (P_DIV_FRAC.EXE) was utilized to manipulate the point-of-diversion water-right file. The water-right file can be queried for specific water uses before calculating the diversion fractions; in this case only irrigation rights were selected.[1] This assumed that minor omissions would not affect the illustrative nature of these simulations. For a simulation evaluating an actual contemplated administrative action, other assumptions could be made.

The program P_DIV_FRAC.exe uses the selected records to produce a new data table listing the fraction of diversion rate within each model cell that is junior to a user-specified priority date. The process was repeated for each of the sample curtailment dates, but any desired date may be analyzed when an actual situation is to be evaluated.

Once consumptive use and ground-water irrigated areas were determined, the data were processed using the Fortran component of the GIS-Recharge Tool, resulting in Modflow Well files, the input files for the ground water model which represents the ground water pumping. The Well files for the long-term curtailment simulations represent the rate of average daily ground water pumping, spread out over a year, for each model cell. The Well files for the seasonal curtailment simulations represent the average net consumptive use alternating for the irrigation season and for the non-irrigation season. One Well file was generated for each of the five desired time periods, for each type of simulation.

Handling of Mixed Source Lands

Mixed source lands, where the same acreage is permitted for both ground water and surface water use, present a particular challenge in this analysis. Acreage has been authorized with both surface water and ground water supplies for multiple reasons. In some cases, the original diversion structures have been replaced by wells but the nominal surface water rights are still recorded, resulting in mixed source authorizations. In other cases, ground water rights have been issued to supplement surface water use during water shortages, but in fact are seldom if ever used.

The amount of benefit gained by curtailing ground water-irrigated areas which are assigned to mixed source lands will be driven by what happens after the curtailment. If the curtailment results in the land not being irrigated, then using consumptive use as an estimate of the benefit of curtailment is reasonable. However, if curtailment of ground water pumping results in an increased use of surface water on the same acreage, then no benefit is seen from curtailment.

In the model calibration, the fraction of supply on mixed-source parcels was partitioned between ground-water and surface-water using a diversion-depth analysis. The fraction of supply is represented in the GIS data by a “source fraction” value. The curtailment of

[1] IWRRI calculations and independent USGS data (Goodell 1988, Maupin 2004) indicate that 95% to 97% of all consumptive use from ground water is associated with irrigation.

ground-water pumping is represented by reducing the source fraction of all ground-water irrigated parcels within a model cell according to the fraction of ground water rights junior to the date of interest, within that model cell. Three methods were tested, as outlined in Appendix C. The method selected was to proportionally reduce the source fraction according to the priority fraction, without consideration of the total amount of supply coming from ground water. This is a simplification of the conceptual model of what actually may occur, but the test shows that results obtained using this method are within 1% of more sophisticated methods that increase opportunities for error and require estimation of additional parameters. Appendix C documents this test.

Running of ESPA Model

Both the steady state and transient versions of the numerical superposition ESPA model were run using the Modflow well files described in the previous section. The steady state model predicts impacts to river reaches after the full effect of the aquifer stress has been realized (essentially after infinite time). The transient model predicts the impacts as they occur over time. The transient ESPA model for the long-term curtailment simulations was set up using 150 1-year stress periods, with each stress period having 5 time steps. The transient ESPA model for the long-term curtailment simulations was set up using 20 6-month stress periods, with each stress period having 3 time steps. A stress period is the period of time during which the representation of aquifer pumping is held constant. A time step is an intermediate calculation point.

As discussed in the previous section, the Modflow well files for the long-term curtailment simulations represent average daily ground-water pumping, applied as continuous pumping for the duration of the model scenario, for each model cell. For the seasonal curtailment scenarios, the Modflow well files represent the net recharge due to precipitation and evapotranspiration for 6-month periods, representing irrigation and non-irrigation seasons, for each model cell.

Determination of Impacts to River Reaches Due to Modeled Ground-Water Pumping

Once the ESPA model is run, a post-processing utility is run to sum river reach impacts for each of the eleven modeled reaches of the Snake River. These results are available for each of the modeled cutoff dates for both steady state and transient simulations. The results are then imported into a Microsoft EXCEL workbook for preparation of resulting graphs and tables.

Appendix B. Irrigated Land and Consumptive Use by Ground-Water District

A request was made for a summary by ground-water district of how many acres and how much consumptive use would be curtailed for each priority date cutoff. No statement is being made in this appendix of plans for curtailment of any particular group of ground-water pumpers. These data are merely being supplied as a courtesy. Figure B-1 shows the map of water districts used for this analysis.

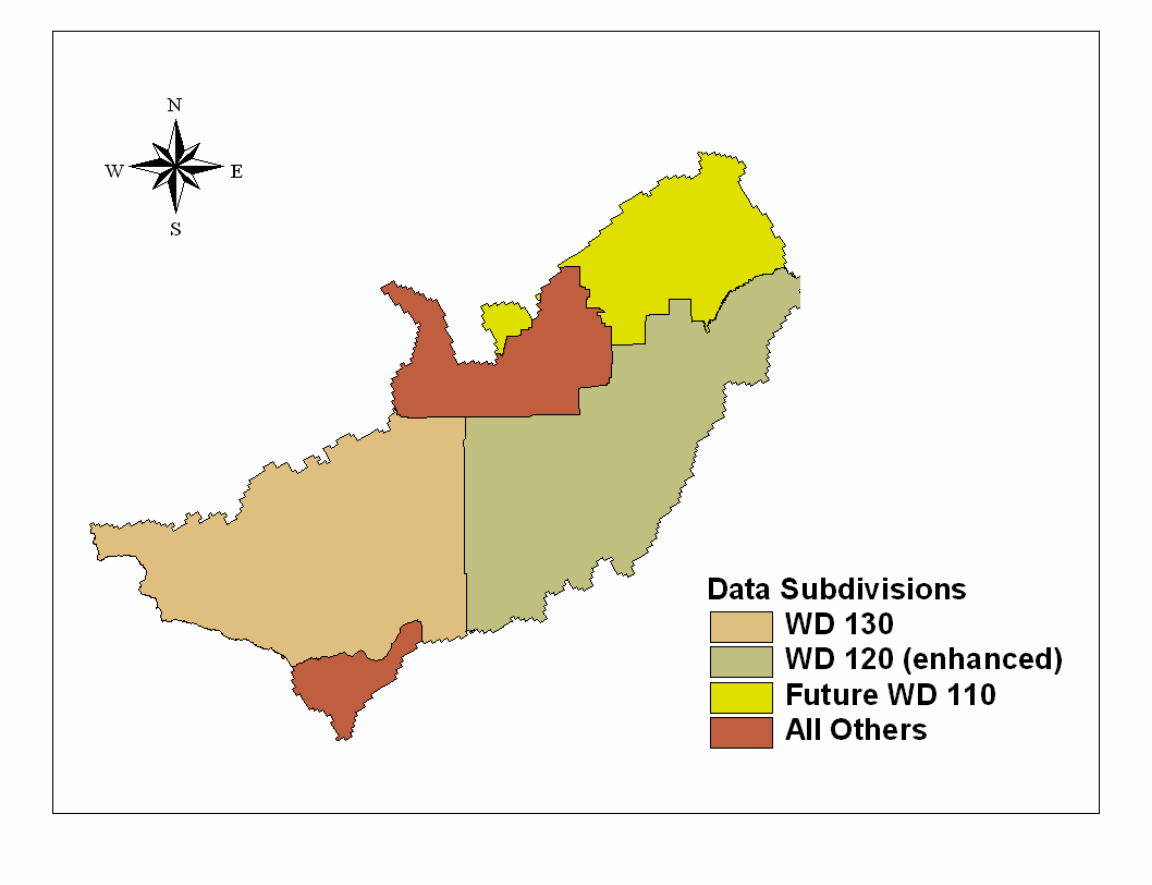

Figure B-1. Ground-water district boundaries used for summary of curtailed acres and consumptive use.

Table B-1 summarizes the number of acres curtailed and the associated consumptive use for each ground-water district for each of the cutoff periods.

Table B-1. Curtailed acres and consumptive use by district.

Appendix C. Analysis of Impact of Mixed Source Lands on Curtailment Scenarios.

When ground-water rights are curtailed, there is an effect on mixed-source lands. Preliminary calculations assumed that the reduction in consumptive use with curtailment is proportional to the fraction of supply from ground water for the area being evaluated. However, it is possible that actual responses will depend on the adequacy of the surface-water supply and the reliance on ground water. To determine the significance of this possibility on curtailment scenarios, three alternate methods of treating mixed-source lands were considered.

The fine black line in Figure C-1 illustrates the conceptual model that the reduction in consumptive use from curtailment is dependent on the fraction of supply from ground water. When ground water is a high fraction of supply, a unit reduction in supply may reduce consumptive use by more than one unit, but when ground water is a low fraction of supply, curtailment may not reduce consumptive use at all.

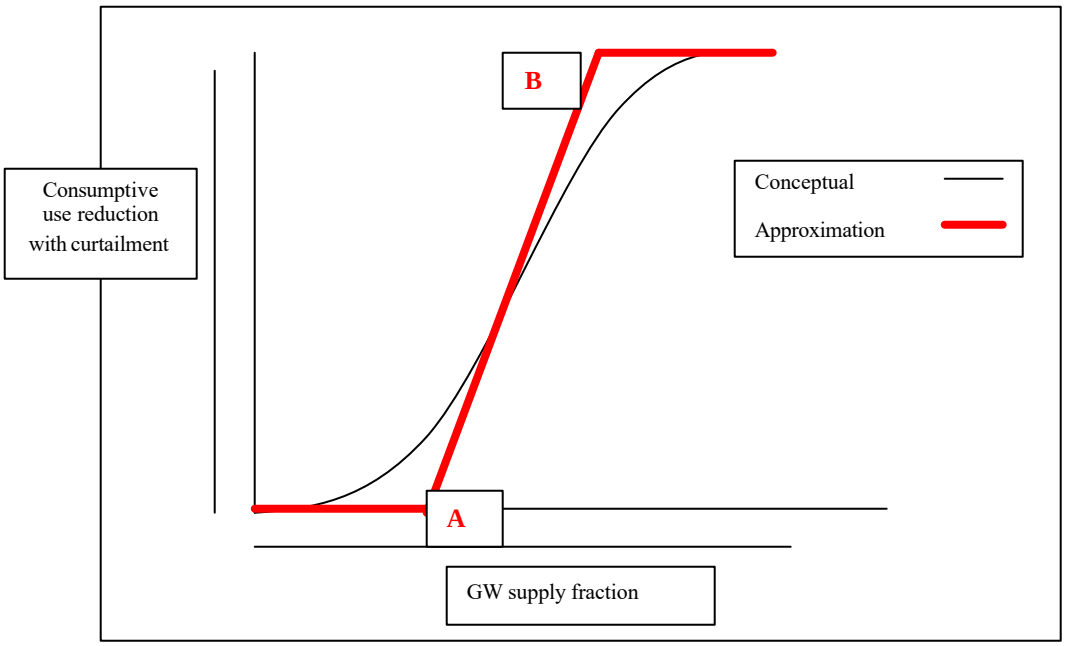

Figure C-1. Conceptual Model

An approximation of the unknown non-linear relationship could be the stepwise-linear relationship illustrated with the heavy red line. The shape of the approximation line is governed by placing of breakpoints A and B. Three pairs of breakpoints "A" and "B" were tested: 1) 0% and 100%, 2) 10% and 90%, 3) 20% and 80%. Option 1 is a straight diagonal line, corresponding to preliminary analyses.

Using GIS analysis of the ground-water-irrigated polygons from model calibration, the three breakpoint pairs were applied to all the ground-water polygons within the study area. Polygons that were ground water only were left with a source fraction of 100%, and mixed-source polygons were scaled according to the following rules:

1. If ground-water fraction is less than breakpoint A, set source fraction to zero. This implies that for parcels with only a small supply of ground water, the response to curtailment will be more careful management of surface water with no reduction in acreage or consumptive use.

2. If ground-water fraction is greater than breakpoint B, set source fraction to 100%. This implies that for parcels almost totally dependent on ground water, curtailment will result in fallowing the entire farm. All consumptive use, even that formerly associated with the small surface-water supply, will cease.

3. If ground-water fraction is between A and B, set the source fraction equal to:

   (GW fraction - A) / (B - A)

   This sets the transition line on a diagonal between the breakpoints.

For the 0%/100% pair, this rule simply set the source fraction equal to the original ground-water fraction from the calibration data. Figure C-2 illustrates the results graphically.

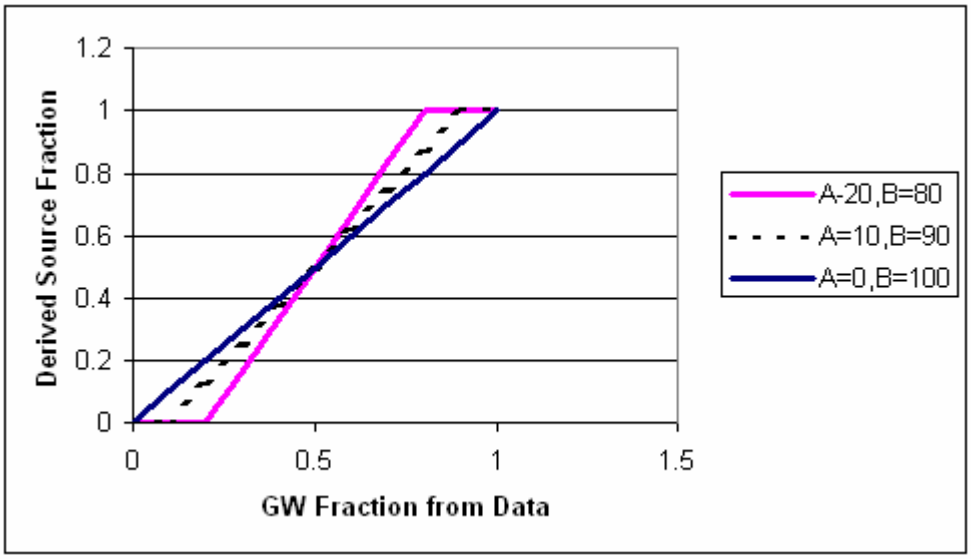

Figure C-2. Results of Calculations.

To test the impact of these three options, acreage was calculated for each polygon. For each polygon, the acreage was multiplied times the three different rule-derived source fractions to obtain the equivalent acreage suggested by the three different rules. To compare results, the effective acreage for all polygons was summed for each option. Table C-1 shows the results:

Table C-1
Results of Test

Breakpoint A	Breakpoint B	Effective Acres	Acres, % of Calibration-period acres
0%	100%	1,111,000	100%
10%	90%	1,120,000	101%
20%	80%	1,125,000	101%

Because the percentages were so similar, the original method was retained. When considering the effect of curtailment on mixed-source lands, the impact on consumptive use is represented as proportional to the fraction of supply from ground water.

Executive Summary

This report was prepared in response to expert reports submitted for the Rangen Delivery Call, which requests curtailment of groundwater users with water right priority dates junior to July 13, 1962 for distribution of water to water rights 36-2551 and 36-7694. A total of 18 expert reports and rebuttal reports were submitted to the Idaho Department of Water Resources (IDWR) on behalf of Rangen, Inc. (Rangen), the Idaho Ground Water Appropriators (IGWA), the City of Pocatello, and Freemont Madison Irrigation District (FMID). The main issues raised by the parties' experts appear to be[1]:

1. Whether Rangen is entitled to make a call based on discharge from the entire spring complex or only discharge from Martin-Curren Tunnel, which is the source listed on the partial decrees for Rangen's water rights.
2. Whether Martin-Curren Tunnel is a surface water source.
3. Whether Rangen is beneficially using available water with reasonable efficiency, or is using water inefficiently and wasting water.
4. Whether Rangen has suffered material injury because of reduced water availability.
5. Whether the economic impact of curtailment outweighs the economic benefit to Rangen and Rangen's right to water.
6. Whether Rangen's water measurement methods are acceptable.
7. Whether Rangen has made sufficient efforts to increase water availability to its facility.
8. Whether ESPAM2.1 is capable of providing a reasonable prediction of the effects of curtailment at the Rangen spring complex, or is only capable of providing predictions to a larger reach.
9. Whether some groundwater users should be excluded from curtailment based on the fraction of their curtailed use that will accrue to springs and river reaches other than Rangen.
10. Whether water that would accrue to springs and river reaches other than Rangen would be wasted.

Several of these issues are legal or policy issues that cannot be appropriately addressed by IDWR technical staff. This memorandum was prepared by IDWR staff with the intent of summarizing the parties' expert reports and providing IDWR staff opinions regarding Rangen's water measurement methods and the use of ESPAM2.1 as a tool to provide information on the hydrologic effects of curtailment of junior groundwater use. IDWR staff contributors to this memorandum included:

[1] This is a summary of the issues identified in the expert and rebuttal reports and is not intended to convey agreement or disagreement regarding the relevancy of these issues.

Between the 1960s and the present, discharge of the Rangen spring complex has decreased in response to changes in the ESPA water budget. These changes include increased groundwater pumping, decreased incidental recharge associated with surface water irrigation, and changes in natural recharge derived from precipitation. Between 1966 and 2011, the average annual discharge at the Rangen spring complex decreased from 51 cfs to 15 cfs. Because the Rangen spring complex is hydraulically connected to the ESPA, it is clear that groundwater pumping has contributed to the decrease in discharge, but decreases in incidental recharge and natural recharge derived from precipitation have also contributed. The portion of the decrease that is attributable to groundwater pumping is more difficult to determine. ESPAM2.1 is a numerical groundwater model that was developed for the purpose of determining the effects of groundwater pumping on discharge to spring and river reaches, such as the Rangen spring cell.

Numerical models are recognized by the U.S. Geological Survey as the most robust approach for predicting the effects of groundwater pumping on surface-water discharge (Barlow and Leake, 2012). A numerical model is able to account for spatial variation in hydrogeologic features and aquifer stresses, and the temporal variation of aquifer stresses. ESPAM2.1 accounts for these features within the constraints of a one-square-mile model grid and one-month stress periods, which is superior to any other predictive method developed for the ESPA to date. Geologic controls on hydrologic responses to aquifer stress are reflected in the discharge and aquifer head data used to calibrate the model. ESPAM2.1, like all groundwater models, is an imperfect approximation of a complex physical system, but it is the best available scientific tool for predicting the effects of groundwater pumping on discharge at the Rangen spring cell and other spring and river reaches. ESPAM2.1 is a regional groundwater model and is suitable to predict the effects of junior groundwater pumping on discharge at the Rangen spring cell because the spring discharge responds to regional aquifer stresses, and junior groundwater pumping is a dispersed, regional aquifer stress.

The parties' experts disagree on whether or not ESPAM2.1 is capable of providing a reasonable prediction of the response to groundwater pumping at the model cell containing the Rangen spring complex. In the opinion of Brockway et al. (2012), the model is capable of predicting the response at the Rangen spring cell. In the opinion of Contor (2012), the model is only capable of providing a reasonable prediction of the response at the Buhl to Lower Salmon Falls reach. Brendecke (2012) appears to offer two opinions. Dr. Brendecke argues that the model prediction of the response at the Rangen spring cell is too uncertain to be used. He also argues that if IDWR uses ESPAM2.1, the steady state response functions, which are the model-predicted responses at the Rangen spring cell to curtailment within individual model cells, should be used to delineate a 10% trimline.

EXHIBIT "504"
Page No. 5 of 81

001952

IDWR staff recommend using ESPAM2.1 as a predictive tool to evaluate the effects of groundwater pumping and curtailment of groundwater pumping on discharge at the Rangen spring cell and to evaluate the portion of curtailed use that will accrue to the Rangen spring cell. ESPAM2.1 predicted responses to curtailment of junior groundwater pumping within various areas are summarized in Table 1. These areas were selected in response to areas or de minimis standards discussed in the parties' expert reports, and are not intended to convey an opinion regarding the use of a trimline and/or the area of common groundwater supply to limit the area of curtailment.

ESPAM2.1 may also be used to predict the effects on discharge in the Buhl to Lower Salmon Falls reach and the portion of curtailed use that will accrue to the reach, as suggested by Contor (2012a). If ESPAM2.1 is not used to predict to the spring cell, apportioning the change in reach gain to the Rangen spring cell would need to be accomplished using an alternative method. The parties' experts did not suggest methods for apportioning the change in reach gain to the Rangen spring complex. IDWR staff evaluated potential alternative methods for predicting effects at the Rangen spring cell, but note that the alternative methods consider fewer data and are less robust than the ESPAM2.1 numerical model.

ESPAM2.1 was developed in an open, collaborative environment, with guidance from the Eastern Snake Hydrologic Modeling Committee (ESHMC). During development of ESPAM2.1, the ESHMC provided a forum for discussing model design, providing parties to this water call (and other interested parties) the opportunity for technical review and input throughout the model development process. Decisions regarding the conceptual model, model grid size, drain elevations, locations of transmissivity pilot points, spring discharge and aquifer head targets, the location of general head boundaries, calibration bounds, and other model features were presented to the ESHMC with opportunity for committee members to provide comments and suggest alternative approaches.

Summary of IDWR staff conclusions

Use of ESPAM2.1 as a predictive tool

1. ESPAM2.1 is the best available scientific tool for answering the following questions that may be relevant to this water call.

    a. What is the effect of junior groundwater pumping within the ESPA on discharge at the Rangen spring cell?

    b. What portion of curtailed groundwater use will accrue to the Rangen spring cell?

    c. What portion of curtailed groundwater use will accrue to other spring cells and reaches of the Snake River?

    d. How long will it take for the effects of curtailment of junior groundwater pumping to reach the Rangen spring cell?

    e. What is the effect of junior groundwater pumping within the ESPA on discharge at the Buhl to Lower Salmon Falls reach?

EXHIBIT "504"
Page No. 6 of 81

001953

2. ESPAM2.1 incorporates the spatial distribution of aquifer recharge and discharge and regional-scale hydrogeology within the constraints of a one-mile square grid size and transmissivity pilot point spacing, which is approximately two to four miles in the vicinity of the Buhl to Lower Salmon Falls reach. The grid and transmissivity pilot point spacing allow ESPAM2.1 to reflect variations in aquifer stress and hydrogeologic properties with greater resolution than other available predictive methods.

3. Junior groundwater pumping within the ESPA occurs over an approximately 11,000 square mile area. The effect of this pumping on springs and river reaches is a regional-scale question that cannot be addressed with a small-scale, local model.

4. ESPAM2.1 was calibrated to over 43,000 observed aquifer water levels, over 2,000 monthly river gain and loss estimates, and over 2,000 monthly spring discharge observations collected from 14 different spring complexes, including 283 monthly spring discharge observations at the Rangen spring cell. These calibration targets reflect the impact of geologic features on hydrologic responses. Because the ESPAM2.1 calibration process considered such a large number of data, ESPAM2.1 is superior to other available predictive methods that consider significantly fewer data.

5. ESPAM2.1 was calibrated to observed monthly discharge data from May 1985 through October 2008 at the Rangen spring cell. The observed discharge is the response to regional aquifer stresses within the ESPA. ESPAM2.1 provides reasonable predictions of the response to changes in regional aquifer stress within the range of stress encountered during the May 1980 through October 2008 simulation period. The Rangen spring complex is the only spring complex in the Rangen model cell.

6. ESPAM2.1 was developed in an open, collaborative environment, with guidance from the Eastern Snake Hydrologic Modeling Committee (ESHMC). During development of ESPAM2.1, the ESHMC provided a forum for discussing model design, providing parties to this water delivery call (and other interested parties) the opportunity for technical review and input throughout the model development process. Decisions regarding the conceptual model, model grid size, drain elevations, locations of transmissivity pilot points, spring discharge and aquifer head targets, the location of general head boundaries, calibration bounds, and other model features were presented to the ESHMC with opportunity for committee members to provide comments and suggest alternative approaches. At the completion of ESPAM2.1, the ESHMC recommended, "*The Eastern Snake Hydrologic Modeling Committee recommends that the Department begin using ESPAM version 2.1 rather than ESPAM version 1.1 for ground water modeling.*" Two members of the committee (Mr. Sullivan and Dr. Brendecke) qualified this recommendation with, "*although other tools or models may be more appropriate in certain circumstances*." Two other members of the committee (Mr. Warner and Mr. Contor) dissented from the recommendation.

EXHIBIT "504"

001954

7. The consumptive use of groundwater associated with irrigation water rights junior to July 13, 1962 within the ESPAM2.1 model boundary averages approximately 1.2 MAF/year. Curtailment of this use would increase net aquifer recharge to a volume within the range encountered during the model calibration period. For example, curtailment of this use during the years 2003-2007 (when average annual net ESPA recharge was approximately 4.4 MAF/year) would increase the net ESPA recharge to 5.6 MAF/year, which was the average annual net ESPA recharge during the years 1993-1997. Therefore, it is important that ESPAM2.1 was calibrated with equal consideration for each observed monthly value at the Rangen spring complex. It would not be appropriate to increase the weight of post-2000 observations during model calibration as suggested by Brendecke (2012, 2013) and Hinckley (2013).

8. Contor (2012a), Hinckley (2012, 2013), and Brendecke (2012, 2013) conclude that ESPAM2.1 does not include sufficient local-scale detail to be capable of providing a reasonable prediction of responses at the Rangen spring cell, but do not suggest alternative methods for estimating the response at the Rangen spring cell. If ESPAM2.1 is used to predict the response at the Buhl to Lower Salmon Falls spring reach, as suggested by Contor (2012a), then an alternative method for apportioning the reach response between the Rangen spring complex and other springs would need to be used. ESPAM2.1 incorporates the spatial distribution of recharge and groundwater pumping, a large number of water level and aquifer discharge observations, regional-scale hydrogeology, and the transient response of aquifer discharge to spatially and temporally distributed recharge and pumping. An alternative approach would likely neglect one or more of these factors and be inferior to using ESPAM2.1 to predict the response at the Rangen spring cell.

9. Steady state response functions for the Rangen spring cell consist of 11,236 model predictions of response at the Rangen spring cell to pumping in a single model cell. If ESPAM2.1 were not capable of providing a reasonable prediction of the effects of model-wide curtailment on discharge at the Rangen spring cell, it would also be incapable of reasonably predicting response functions for the Rangen spring cell and would not be able to provide a reasonable prediction of the location of the 10% trimline that Brendecke (2012) proposes.

10. Whether a trimline should be applied, and the basis for delineating a trimline, are policy and/or legal decisions. If a trimline is based on steady state response functions, as proposed by Brendecke (2012), the trimline delineates an area within which the portion of curtailed use that will accrue to the Rangen spring cell exceeds a given threshold percentage. Groundwater users outside of this area would be excluded from curtailment because the portion of their curtailed use that accrues to the Rangen spring cell is predicted to be less than the threshold percentage.

11. The ESPAM2.1 predicted response functions used to delineate the 10% trimline proposed by Dr. Brendecke are subject to the same types of model uncertainty as the ESPAM2.1 predicted response to model-wide curtailment. Use of the steady state response functions to delineate a trimline requires accepting that the ESPAM2.1 provides the best available prediction of response at the Rangen spring cell.

EXHIBIT "504"
Page No. 8 of 81

001955

12. Delineation of a trimline based on steady state response functions is a direct application of ESPAM2.1-predicted responses, and is not an "*adjustment to model predictions*" as suggested by Brockway et al. (2012, 2013).

13. ESPAM2.1 is an improvement to ESPAM1.1, which was used as a tool to predict the effects of groundwater pumping, curtailment, and mitigation practices for administration of previous ESPA water calls.

ESPAM2.1 predictions

1. ESPAM2.1 predicted responses to junior groundwater curtailment within various areas are summarized in Table 1. These areas were selected in response to areas or de minimis standards discussed in the parties' expert reports, and are not intended to convey an opinion regarding the use of a trimline and/or the area of common groundwater supply to limit the area of curtailment.

2. ESPAM2.1 predicts that a model-wide curtailment of groundwater irrigation junior to July 13, 1962 would increase discharge at the Rangen spring cell by 17.9 cfs and reach gains in the Buhl to Lower Salmon Falls reach by 242 cfs at steady state. It would take approximately 13 years to reach 90% of the steady state response. The simulated curtailment would affect approximately 565,000 acres and would increase net aquifer recharge by approximately 1.2 MAF/year (1,705 cfs). The benefit predicted at the Rangen spring cell is only 1% of the curtailed use. The other 99% of the benefit would accrue to other springs and reaches of the Snake River. The predicted benefit to the Buhl to Lower Salmon Falls reach is 14% of the curtailed use. This curtailment simulation includes areas located outside of the current area of common groundwater supply.

3. Based on comparison of the historic response of the Rangen spring complex to changes in net recharge to the ESPA, the ESPAM2.1 predicted response of 17.9 cfs to a 1.2 MAF/year increase in net recharge appears to be reasonable. Rangen discharge data indicate that spring discharge decreased approximately 35 cfs between 1966 and 2007, in response to a decrease in average annual net recharge of approximately 1.7 MAF. Linear regression of Rangen spring complex discharge with a 5-year trailing average of net ESPA recharge indicates that spring discharge has historically changed by approximately 13 cfs per MAF change in the ESPA water budget (Figure 1), indicating that the response to a 1.2 MAF decrease in consumptive groundwater use should result in an increase on the order of 16 cfs in spring discharge. IDWR staff consider this predictive method inferior to ESPAM2.1, but it does provide a "reality check" that indicates the ESPAM2.1 prediction is not unreasonable given historic responses observed at the Rangen spring complex.

EXHIBIT "504"
Page No. 9 of 81

001956

Area of curtailment	Predicted increase in discharge (cfs)			Portion of curtailed use accrued to reach (%)		
	Rangen spring cell	Buhl to Lower Salmon Falls reach[2]	Buhl to Lower Salmon Falls springs[3]	Rangen spring cell	Buhl to Lower Salmon Falls reach	Other reaches
Model domain	18	242	236	1%	14%	86%
Area of common groundwater supply (ACGW)	17	229	223	1%	15%	85%
10% trimline based on response at Buhl to Lower Salmon Falls reach (within ACGW)	15	198	193	3%	34%	66%
5% trimline based on response at Rangen cell	3.3	29	28	7%	59%	41%
10% trimline based on response at Rangen cell	0.01	0.08	0.08	13%	81%	19%

Table 1. Summary of ESPAM2.1 predicted responses to curtailment of groundwater irrigation junior to July 13, 1962.

[2] Includes increase in base flow modeled at general head boundaries.
[3] Excludes increase in base flow modeled at general head boundaries.

EXHIBIT "504"
Page No. 10 of 81

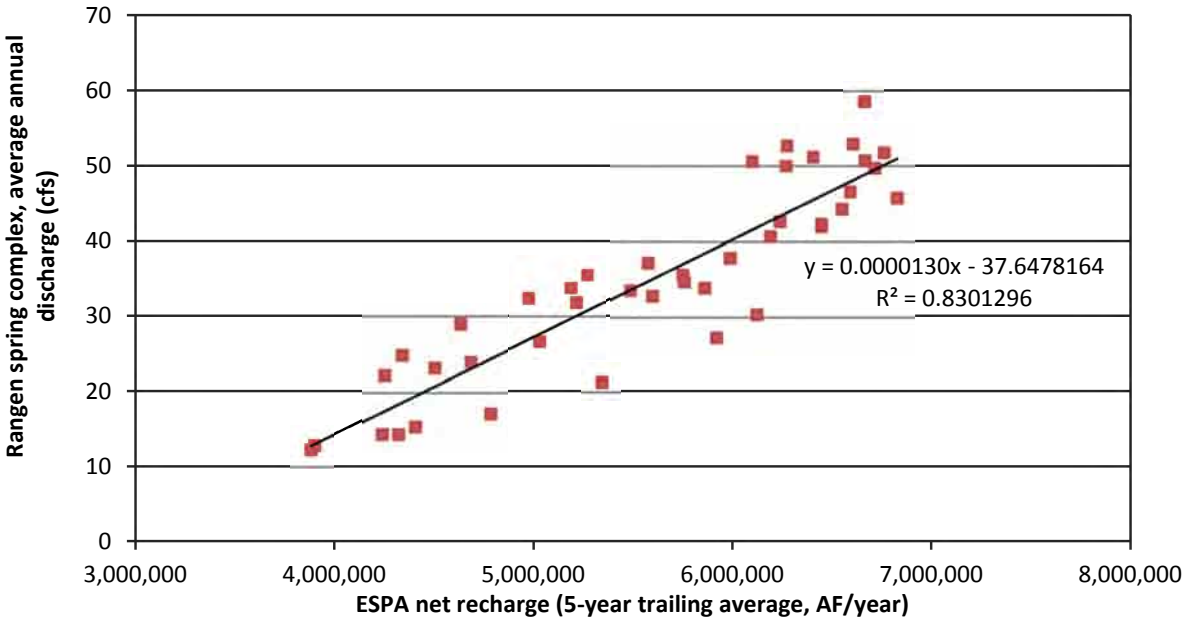

Figure 1. Comparison of average annual discharge at Rangen spring complex with net ESPA recharge.

4. ESPAM2.1 steady state response functions (Figure 2) indicate that discharge in the Rangen spring cell responds to stresses dispersed throughout the ESPA. Collectively, model-wide groundwater pumping has a significant effect on discharge at the Rangen spring cell, but more than 84% of the effects of groundwater pumping in any individual model cell propagate to other springs or reaches of the Snake River. The percentage of the effects of groundwater pumping that accrue to the Rangen spring cell generally decreases as distance from Rangen increases. Less than 1% of the effects of groundwater pumping east of the Great Rift[4] accrue to the Rangen spring cell.

5. If simulation of curtailment of groundwater irrigation is limited to the current area of common groundwater supply, ESPAM2.1 predicts that the benefit to the Rangen spring cell would be 16.9 cfs and the benefit to reach gains in the Buhl to Lower Salmon Falls reach would be 229 cfs. It would take approximately 11 years to reach 90% of the steady state response. The simulated curtailment would affect approximately 479,000 acres and would increase net recharge by approximately 1.1 MAF/year (1,509 cfs). The benefit predicted at the Rangen spring cell is only 1% of the curtailed use. The other 99% of the benefit would accrue to other springs and reaches of the Snake River.

[4] The Great Rift extends north to south across the plain from the Big Lost River Valley to just west of American Falls Reservoir. The transmissivity of the Great Rift is low relative to adjacent areas of the ESPA (IDWR, 2013).

EXHIBIT "504"
Page No. 11 of 81

001958

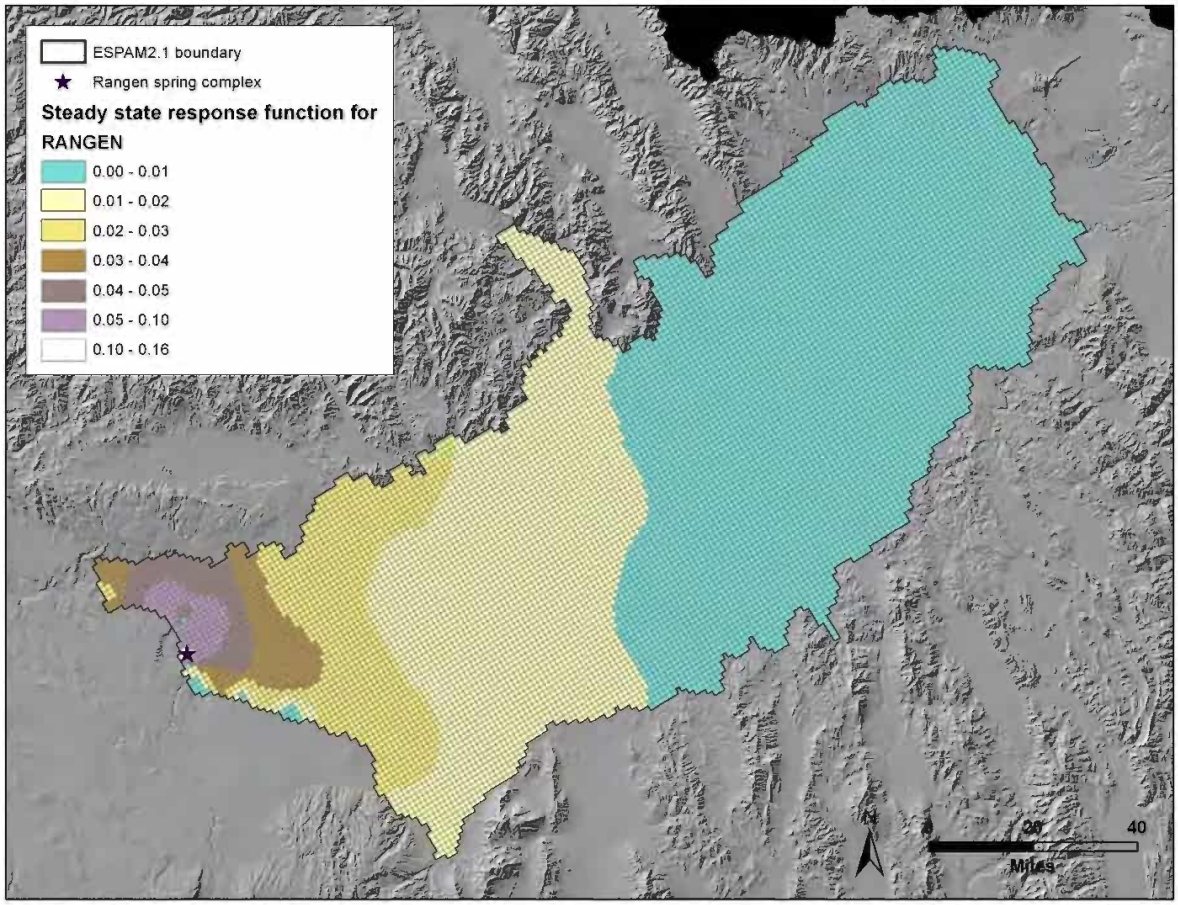

Figure 2. Steady state response functions indicating the portion of curtailed use that would accrue to the Rangen spring cell.

6. If simulation of curtailment of groundwater irrigation is limited to areas where at least 10% of the benefit is predicted to occur at the Rangen spring complex, ESPAM2.1 predicts that the benefit will be negligible (0.01 cfs).

7. If simulation of curtailment of groundwater irrigation is limited to areas where at least 5% of the benefit is predicted to occur at the Rangen spring complex, ESPAM2.1 predicts that the benefit would be 3.3 cfs. The simulated curtailment would affect approximately 12,300 acres and would increase net aquifer recharge by approximately 36,000 AF/year (49.6 cfs). Approximately 7% of the benefit would accrue to the Rangen cell, the other 93% would accrue to other springs and river reaches.

8. If simulation of curtailment of groundwater irrigation is limited to areas within the area of common groundwater supply where at least 10% of the benefit is predicted to occur at springs within the Buhl to Lower Salmon Falls reach, ESPAM2.1 predicts reach gains in the Buhl to Lower Salmon Falls reach would increase by 198 cfs and spring discharge at the Rangen cell would

EXHIBIT "504"
Page No. 12 of 81

001959

increase by 14.7 cfs. The simulated curtailment would affect approximately 169,000 acres and would increase net aquifer recharge by approximately 419,000 AF/year (578 cfs). Approximately 34% of the curtailed use would benefit the Buhl to Lower Salmon Falls reach, and approximately 2.5% would benefit the Rangen cell.

9. ESPAM2.1 was calibrated to total discharge at the Rangen spring cell, and is not capable of predicting the effects of curtailment on Curren Tunnel discharge and other spring discharge separately. If there is a need to predict the effects of curtailment on tunnel discharge, IDWR staff recommend using the slope of the linear regression of tunnel discharge with total spring complex discharge. This method indicates that the response at the tunnel will be 70% of the total response (i.e., the predicted response at the tunnel would be 12.5 cfs for model-wide curtailment, 11.9 cfs for the area of common groundwater supply, 2.3 cfs for a 5% trimline, and negligible for a 10% trimline).

Model uncertainty

1. The ESPAM2.1 predicted responses to curtailment at the Rangen spring complex and the Buhl to Lower Salmon Falls spring reach are the best available predictions. Because of predictive uncertainty associated with using the model, the actual response may be lower or higher than the prediction. Predictive uncertainty was evaluated by Wylie (2012a). Model uncertainty was evaluated Contor (2012a, 2012b), and Brendecke (2012).

2. Wylie (2012a) evaluated the uncertainty of the ESPAM2.1 calibration with respect to predictive uncertainty at the Clear Lakes spring cell. None of the analyses involving Clear Lakes resulted in significant uncertainty.

3. The ESPAM2.1 calibration procedure allowed adjustment of several components of the water budget (including evapotranspiration, tributary underflow, recharge on non-irrigated lands, canal seepage, and non-Snake River seepage) within ranges of uncertainty determined by the ESHMC. The IDWR predictive uncertainty analysis (Wylie, 2012a) incorporated the impact of uncertainty associated with these components of the water budget on predictive uncertainty.

4. Contor (2012a) concluded that model uncertainty is at least 17%, based on uncertainty of the water budget input data. IDWR staff note that not all sources of uncertainty significantly impact every prediction. This is illustrated by the IDWR predictive uncertainty analysis (Wylie, 2012a), which incorporated the uncertainty associated with many of the components of the water budget and indicated that predictive uncertainty is low with respect to the response at the Clear Lakes spring cell. Further, a 17% increase or decrease (as suggested by Contor, 2012a) in the predicted response to curtailment at the Rangen spring complex would only be a change of 3 cfs (i.e. 17.9 cfs $\pm$ 17% would be a range of 14.9 to 20.9 cfs).

5. Brendecke (2012) evaluated conceptual model uncertainty by developing two alternative models that he asserts better represent local conditions in the vicinity of the Rangen spring cell. IDWR staff simulated a model-wide curtailment with these models and found that the models

EXHIBIT "504"
Page No. 13 of 81

001960

predicted responses of 18.5 cfs and 18.0 cfs at the Rangen spring cell. These responses are less than 0.6 cfs different from the response of 17.9 cfs predicted by ESPAM2.1.

6. IDWR staff also used Dr. Brendecke's alternative conceptual model to simulate the response to curtailment within the four mile square area located within a 10% trimline defined using ESPAM2.1 predictions of responses at the Rangen spring cell. The response to this curtailment simulation was a negligible amount of water (0.01 cfs) using both alternative models and ESPAM2.1.

7. The evaluations of model uncertainty performed by Contor (2012a, 2012b) and Brendecke (2012) have not been subjected to peer review by the ESHMC, and IDWR staff disagree with some of the methods used and conclusions drawn by these parties.

8. The evaluations performed by IDWR and the parties' experts are partial evaluations of model uncertainty and do not fully explore or quantify all aspects of model uncertainty. These evaluations do not contradict IDWR's conclusion that ESPAM2.1 is capable of providing a reasonable prediction of the response to groundwater pumping at the Rangen spring cell. These evaluations also do not contradict IDWR's conclusion that ESPAM2.1 is the best available scientific tool to estimate the quantity of the response.

Consideration of alternative predictive methods

1. Contor (2012a), Hinckley (2012), and Brendecke (2012) conclude that ESPAM2.1 does not include sufficient local-scale detail to be capable of providing a reasonable prediction of responses at the Rangen spring complex, but do not propose alternative methods for predicting the effects of curtailment of junior groundwater pumping at Rangen. IDWR staff considered the following alternative predictive methods.

    a. Do not predict the effects of curtailment. This alternative provides the hearing officer with no information regarding the magnitude of effects of curtailment at Rangen or other springs and river reaches, no information for delineating an area of de minimis effects, and no information regarding potential mitigation requirements or the effects of proposed mitigation plans.

    b. Use ESPAM2.1 to predict the response at springs within the Buhl to Lower Salmon Falls reach and use an inferior method to estimate the portion of the reach gains that would benefit the Rangen spring complex.

        i. Use the Covington and Weaver ratio method previously used with ESPAM1.1 to apportion discharge to the Rangen spring complex. This method results in a predicted accrual of 2.9 cfs at the Rangen spring complex in response to model-wide curtailment, and 2.4 cfs in response to curtailment within a 10% trimline for the reach. This method is inferior to using the ESPAM2.1 prediction for the Rangen spring cell, because it considers fewer data than ESPAM2.1, neglects

EXHIBIT "504"
Page No. 14 of 81

regional hydrogeologic conditions that are included in ESPAM2.1, neglects the spatial distribution of aquifer recharge and discharge, and neglects the sensitivity of higher elevation springs to changes in aquifer head.

ii. Use a linear regression of Rangen spring complex discharge with reach gain to predict change in Rangen spring discharge corresponding to the modeled change in reach gain. This method results in a predicted accrual of 6.8 cfs at the Rangen spring complex in response to model-wide curtailment and 5.5 cfs in response to curtailment within a 10% trimline for the reach. This method is inferior to using the ESPAM2.1 prediction for the Rangen spring cell, because it considers fewer data than ESPAM2.1, neglects regional hydrogeologic conditions that are included in ESPAM2.1, and neglects the spatial distribution of aquifer recharge and discharge.

c. Use ESPAM2.1 to predict the response at Well 989, which is the closest head target and water level change target to the Rangen spring cell, located approximately ½ mile northeast of the Rangen spring complex. Use a linear regression of observed Rangen spring complex discharge with observed water level elevation to evaluate the response at the Rangen spring complex to change in head at Well 989. This method predicts accrual of 16.5 cfs at the Rangen spring complex in response to model-wide curtailment. This method considers nearly all of the data used by ESPAM2.1, but the correlation between Well No. 989 and Rangen spring discharge does not consider the transient response time between the two locations.

d. Use a linear regression between observed Rangen discharge and the estimated annual net recharge to the ESPA to predict the response to curtailment. This method is inferior to ESPAM2.1 because it considers far fewer data than ESPAM2.1, neglects regional hydrogeologic conditions that are included in ESPAM2.1, and neglects the spatial distribution of aquifer recharge and discharge. This method predicts a response of 16.1 cfs to a model-wide curtailment of junior groundwater irrigation.

2. ESPAM2.1, like many other groundwater models, was developed as a tool to answer questions that could not be addressed adequately with other predictive methods. The groundwater model is able to incorporate more observed data than other predictive methods, and can calibrate hydrogeologic properties that cannot be measured to best fit the observed data. ESPAM2.1 is the best developed scientific tool for predicting the effects of junior groundwater pumping on the Buhl to Lower Salmon Falls spring reach and at the Rangen spring complex.

3. Numerical models are recognized by the U.S. Geological Survey as the best approach for predicting the effects of groundwater pumping on surface-water discharge. The U.S. Geological Survey states, "*Numerical models provide the most robust approach for determining the rates, locations, and timing of streamflow depletion by wells*." (Barlow and Leake, 2012). The use of a numerical model, like ESPAM2.1, is able to account for the irregular geometry of aquifer

EXHIBIT "504"
Page No. 15 of 81

001962

boundaries, irregular geometry of rivers and spring locations, heterogeneous aquifer properties, and time-varying aquifer stresses applied at various locations within a basin. ESPAM2.1 accounts for these features within the constraints of a one-square-mile model grid, the transmissivity pilot point spacing, and one-month stress periods, which is superior to any other predictive method developed for the ESPA to date.

Adequacy of Rangen discharge measurements

1. Rangen submitted annual water measurement reports directly to IDWR from 1995 through 2009, and to Water District 36A from 2010 to 2012. IDWR has accepted these annual water measurement reports during this period of record understanding that Rangen estimates hatchery diversions or flows using fish raceway check boards as non-standard weir measuring devices.

2. Check board weirs are not considered standard measurement devices. IDWR's *Minimum Acceptable Standards for Open Channel and Closed Conduit Measuring Devices* specify that construction, installation and operation of open channel measuring devices, including contracted rectangular weirs and suppressed rectangular weirs, should follow published guidelines such as those published by the United States Bureau of Reclamation (USBR, 1997).

3. Although the raceway check boards are not considered standard measuring devices, IDWR accepts measurements using these structures at Rangen and many hatcheries in the area because IDWR's standards allow an accuracy of +/-10 percent for open channel measuring devices when compared to measurements using standard portable measuring devices. Rangen likely under-measures actual flows, but an error up to -10% is acceptable pursuant to IDWR's *Minimum Acceptable Standards for Open Channel and Closed Conduit Measuring Devices.*

4. The calibration target used for ESPAM2.1 was submitted to the ESHMC for review and comment in the fall of 2009. ESHMC members were provided the opportunity to review and comment on the proposed calibration target during development of ESPAM2.1.

5. Systematic under-measurement of discharge at the Rangen spring cell by 10% would be expected to result in slightly lower model predictions of discharge and response to curtailment at the Rangen spring cell. This would favor the groundwater users, not Rangen.

Summary of expert reports

This section summarizes and responds to the following expert reports submitted in the Matter of Distribution for Water to Water Right Nos. 36-02551 and 36-07964, hereafter referred to as the Rangen Delivery Call.

1. Brockway, C.E., D. Colvin, and J. Brannon, 2012. *Expert Report in the Matter of Rangen, Inc. – Availability of Spring Flow and Injury to Water Rights*, prepared for Rangen, Inc., December 20, 2012.
2. Smith, C. E., 2012. *Expert Report in the Matter of Distribution of Water to Rangen, Inc's Water Right Nos. 36-02551 and 36-07694*, prepared for Rangen, Inc.
3. Hinckley, B., 2012. *Rangen Groundwater Discharge and ESPAM2.1 Hydrogeologic Investigation*, prepared for Racine, Olson, Nye, Budge, and Bailey, Chartered, December 20, 2012.
4. Brendecke, C.M., 2012. *Hydrology, Water Right and Groundwater Modeling Evaluation of Rangen Delivery Call*, prepared for Racine, Olson, Nye, Budge, and Bailey, Chartered, December 21, 2012.
5. Rogers, T.L., 2012. *Expert Witness Report by Thomas L. Rogers, Fisheries Biologist/Fish Culturist,* prepared on behalf of the Idaho Ground Water Appropriators, Inc., December 21, 2012.
6. Church, J.S., 2012. *Expert Witness Report by John S. Church, Economist*, prepared on behalf of the Idaho Ground Water Appropriators, Inc., December 21, 2012.
7. Contor, B.A., 2012a. *Technical Report on ESPAM2.0 Modeling Issues*, prepared for Fremont Madison Irrigation District, October 1, 2012.
8. Contor, B.A., 2012b. *Supplement to Technical Report on ESPAM2.0 Modeling Issues*, prepared for Fremont Madison Irrigation District, December 13, 2012.
9. Sullivan, G.K., 2012. *Spronk Water Engineers, Inc. Expert Report in the Matter of Distribution for Water to Water Right Nos. 36-02551 and 36-07694 (Rangen, Inc.)*, prepared for the City of Pocatello, December 21, 2012.

Summary of expert reports submitted on behalf of Rangen, Inc. (Rangen)

Brockway et al. (2012) provide brief descriptions of eastern Snake Plain aquifer (ESPA) geology and hydrogeology, the historical response of the ESPA to changing water use, the history of the Rangen Hatchery, and the history of Rangen's delivery calls. The report addresses historical water availability at the Rangen Hatchery, water measurement procedures, and provides a brief discussion of alternatives Rangen has evaluated for increasing water supply. The report discusses the development of ESPAM2.1, evaluates IDWR tools developed for simulating curtailment of junior groundwater pumping with ESPAM2.1, and evaluates the algorithm used to represent spring discharge in ESPAM2.1. The report also discusses incidental benefits to other water users resulting from the requested curtailment.

EXHIBIT "504"
Page No. 17 of 81

001964

Regarding adequacy of measurement, Brockway et al. (2012) state that Rangen applies a modified weir coefficient to calculate discharge from stage measured over 2-inch thick boards at the CTR raceways and Lodge Pond Dam. They state this is consistent with standard practice at aquaculture facilities.

Brockway et al. (2012) indicate that Rangen has evaluated six alternatives for increasing water supply to the hatchery. The first alternative, diverting water formerly used for agricultural irrigation, was implemented after construction of the Sandy Pipeline. The other alternatives considered included withdrawing water from vertical wells, constructing a horizontal well below the Curren Tunnel, diverting water from the Weatherby Springs/Hoagland Tunnel complex, reducing possible downward flow through existing wells upgradient of Curren Tunnel, treating and re-using hatchery tailwater. The report provides explanations for why these five alternatives are not considered feasible.

Brockway et al. (2012) present results of one modeling simulation performed using the ESPAM2.1. Input data were processed using tools and methodology developed by IDWR for simulating curtailment of groundwater irrigation. Curtailment of groundwater irrigation junior to July 13, 1962 was simulated using ESPAM2.1 in superposition mode. The simulation predicts 17.9 cfs will accrue to the Rangen spring complex at steady state, in response to curtailment of junior groundwater irrigation within the ESPAM2.1 model boundary.

Brockway et al. (2012) present correlations of the Rangen spring complex discharge with water levels measured in seven wells to demonstrate the relationship between aquifer head and spring discharge. They conclude that this analysis demonstrates that Rangen spring complex responds to regional aquifer head, and that this response supports use of ESPAM2.1 to predict responses to changes in aquifer head at the Rangen spring complex.

Brockway et al. (2012) provided sixteen statements of opinion on pages 26 and 27 of their report. Selected points are summarized in this paragraph. In their opinion, the exercise of Rangen's water rights has been impacted by junior groundwater rights, Rangen is appropriately measuring and using available spring flow, Rangen does not have feasible alternatives for increasing water flow through the hatchery via either alternative sources or reuse of hatchery tailwater, and curtailment to mitigate injury to a senior water right is not a waste of the water resource. In their opinion, ESPAM2.1 is the best available science and the IDWR tools and methodology developed for simulating curtailment are sufficient for calculating the impacts of curtailment on water levels and spring flows. Their simulation of curtailment of groundwater pumping junior to July 13, 1962 within the ESPAM2.1 model boundary resulted in a predicted steady state impact of 17.9 cfs at the Rangen spring complex. In their opinion, this prediction is the best available prediction and should not be modified or adjusted using estimates of model uncertainty.

Smith (2012) provided opinions on beneficial use of the water supply currently available to Rangen, and addressed Rangen's ability to put additional water to beneficial use. Mr. Smith visited the hatchery in July and October 2012, and stated that Rangen was using all of the available water to raise fish and conduct research. Mr. Smith stated that 20 of 20 small raceways, 21 of 30 large raceways, and 6 of 9 CTR raceways were unused because of insufficient water flow. Mr. Smith provides additional detail

EXHIBIT "504"
Page No. 18 of 81

001965

regarding Rangen's use of water to raise fish for research testing of fish feeds and for sale to Idaho Power Company. Mr. Smith states that Rangen currently orders eggs only three times per year because of low water flows, and that trout eggs must be ordered one to two years in advance. Mr. Smith states that fish production is constrained by fish loadings (lbs/gpm of water flow) and fish densities (lbs/ft^3 of space) and acknowledges that the allowable loading and density for rainbow trout currently raised for sale to Idaho Power Company are lower than required for fish sold to processors. Mr. Smith notes that Idaho Power Company pays a higher price per pound than local processors.

Mr. Smith states that water currently being used at the Rangen hatchery is of excellent quality, having optimum temperature for growth of rainbow trout (59-60° F), pH between 7.8 and 8.1, hardness of approximately 130 ppm as $CaCO_3$, and is saturated with dissolved oxygen. Mr. Smith concluded that Rangen is using all of the currently available water in a reasonable manner to raise fish, and that Rangen could raise more fish and/or conduct more research if more water was available.

Summary of expert reports submitted on behalf of Idaho Ground Water Appropriators, Inc. (IGWA)

Hinckley (2012) evaluates geology and hydrogeology in a study area encompassing Thousand Springs to Malad Gorge and the Wendell area and evaluates the ESPAM2.1 representation of this area. Mr. Hinckley concludes that ESPAM2.1 does not adequately represent the details and complexity of geologic and hydrogeologic conditions in his study area, and that there is "*considerable uncertainty in the use of the ESPAM2.1 to inform detailed hydrologic analyses of the groundwater discharges at Rangen*." Mr. Hinckley concludes that the Curren Tunnel is a horizontal flowing well that was not constructed to maximize sustainable, year-round production. Mr. Hinkley concludes that "*there are opportunities to develop substantially more robust access to quantities of groundwater to those historically measured at the Curren Tunnel*" by moving the point of diversion and constructing a vertical well above the rim in the area east of Rangen.

Brendecke (2012) discusses hydrology of the Eastern Snake Plain, water rights for the Rangen Hatchery, ESPAM development, simulation of curtailment of junior water rights, and model uncertainty. Dr. Brendecke provides 87 conclusions in Section 1.3 of his report; selected points are summarized in this paragraph. Dr. Brendecke concludes that the source for water rights 36-2551 and 36-7694 is the Martin-Curren Tunnel, which he argues meets the definition of a well, and implies that Rangen does not have a right to divert from the "*natural springs*" that have also historically supplied the hatchery. Dr. Brendecke concludes that water shortages should be evaluated with respect to historic flow in the Martin-Curren Tunnel, not historic diversions to the hatchery. Dr. Brendecke argues that ESPAM2.1 is not capable of separating the effects of groundwater pumping on flows from Martin-Curren Tunnel from other springs in the Rangen complex, and that ESPAM2.1 is not sufficiently detailed in its general formulation or its representation of hydrogeologic conditions at Rangen to be used reliably to predict effects of curtailment at Rangen. Dr. Brendecke presents two alternative calibrated models, which he asserts better reflect hydrogeologic conditions near Rangen. Dr. Brendecke claims that benefits predicted at Rangen using his alternative models are significantly less than predicted by ESPAM2.1, and

EXHIBIT "504"
Page No. 19 of 81

001966

argues these models illustrate the potential effects of conceptual model uncertainty on predicted responses at the Rangen spring complex. Although Dr. Brendecke argues that ESPAM2.1 is not sufficiently detailed to be used reliably to predict effects of curtailment at Rangen, Dr. Brendecke does not propose other tools, models, or methodology for predicting these effects. Dr. Brendecke concludes that "*application of ESPAM2.1 should at a minimum restrict curtailment to junior rights for which ESPAM2.1 predicts at least 10% of the curtailed water will accrue to Rangen*", and that any curtailment of groundwater is a waste of the water resource because the majority of the foregone use would not accrue to Rangen.

Rogers (2012) discusses fish hatchery operation, operations at the Rangen Hatchery, and hypothetical fish-rearing scenarios. Mr. Rogers notes the Rangen hatches eggs in incubators and the fry are reared in troughs until they are large enough to be moved to the small raceways. As the fish grow and approach maximum density or flow indices in the small raceways, they are transferred to the large raceways. According to Mr. Rogers, Rangen currently rears triploid (sterile) rainbow trout under contract to Idaho Power Company (IPCO). The fish are released for sport fishing. Mr. Rogers states that Rangen also continues to perform research related to fish feed, fish flesh, color development and disease, and that Rangen sells some excess rainbow trout on the spot market. Mr. Rogers states that the IPCO contract requires adherence to strict water flow and fish density guidelines, which is consistent with a conservation hatchery program because of the desire to produce good quality fish with increased ability to survive in the natural environment. Mr. Rogers also states that the IPCO contract, which requires fish be ready for release in the months of May and June, prevents Rangen from timing the production cycle to coincide with seasonal fluctuations in water flow. Mr. Rogers concludes that Rangen could raise more fish if flow and density standards, and timing of the production cycle, were not dictated by Rangen's contract with IPCO.

Rogers (2012) concludes that even with the density restraints imposed by the IPCO contract, Rangen could raise more fish with its current water flows. Mr. Rogers bases his analysis on one lot of fish reared in 2011-2012. He states that constraints on production due to water quality generally occur during final rearing, when the fish are largest in size. He also states that estimates at the end of the rearing cycle in the large raceways noted a Density Index of 0.295 and a Flow Index of 0.74, which were below the maximum levels of 0.3 and 0.8 required by the IPCO contract. Mr. Rogers also provides analyses of how many additional fish could be reared if less restrictive Density and Flow Indices were used.

Rogers (2012) offers two suggestions for maximizing water supply to the hatchery. These suggestions include pumping water from Rangen's lower diversion up to the small raceways and developing wells in the ESPA above the canyon rim.

Church (2012) discusses the economics of rearing trout for food, Rangen's grant applications under the Eastern Snake Plain Aquifer Assistance Grants program, grant applications from other spring users, and the economic impacts of curtailment of groundwater irrigation. He asserts that Rangen should have implemented some of the measures outlined in these grant applications. Mr. Church concludes, "*Clearly Rangen has not expended even a minimum effort…to more efficiently use or to augment the waters available to its facility*," and, "*it would be absurd to curtail ground water use in order to fractionally*

EXHIBIT "504"
Page No. 20 of 81

001967

increase water flows to Rangen, without first requiring Rangen to undertake efforts on its own to augment or more efficiently use its water supply by employing measures that are available and have been utilized at other aquaculture facilities."

Summary of expert reports submitted on behalf of Freemont Madison Irrigation District (FMID)

Contor (2012a) was submitted on October 1, 2012 and is based on analyses performed using ESPAM2.0. Mr. Contor states that the determination and application of a de minimis threshold is a policy question, and that a de minimis policy could be defined in terms of a threshold fraction below which propagating effects are considered de minimis, or in terms of a threshold total volume per time, below which effects are considered de minimis. Either approach could be implemented using ESPAM.

Contor (2012a) simulated benefits to the Buhl to Lower Salmon Falls reach from curtailment of groundwater irrigation on the Egin Bench using ESPAM2.0. Using ESPAM2.0, Mr. Contor predicted the cumulative benefit to the Buhl to Lower Salmon Falls reach from curtailment on the Egin Bench junior to July 13, 1962 is 1.90 AF after 150 years, or 0.04% of the curtailed volume. Contor (2012b) concludes that the differences between ESPAM2.0 and ESPAM2.1 do not appear to substantially change the model results relied upon in Contor (2012a). Mr. Contor did not submit an analysis using ESPAM2.1.

Contor (2012b) recommends that ESPAM results be applied using Administrative Reaches that are comprised of entire Calibration Reaches and are no smaller than the distance between nearby transmissivity pilot points. He asserts this will greatly reduce uncertainty (p. 7). He also recommends that administrative decisions that hinge on the timing of arrival of effects be strongly informed by both the short-term temporal performance of the model during calibration and that great caution be exercised whenever administrative outcome is sensitive to timing differences shorter than approximately four months.

Contor (2012b) provides discussions of temporal and spatial uncertainty, the effect of uncertainty, and potential sources of uncertainty. He concludes that the uncertainty arising from the water budget is likely at least 17%, and that overall uncertainty exceeds this estimate. Mr. Contor concludes that uncertainty will always decrease as questions are asked on larger spatial scales and longer cumulative time scales.

Summary of expert reports submitted on behalf of the City of Pocatello

Sullivan (2012) discusses the Rangen Hatchery facilities, water rights for the hatchery and other diversions from the Curren Tunnel, historical flow records, Rangen fish production data, and the City of Pocatello's water rights and water use.

Mr. Sullivan concludes that the Rangen facility has a capacity of slightly greater than 50 cfs, which is the combined flow rate of Rangen's 1957 and 1962 priority water rights. Mr. Sullivan notes that the decreed source of water for the Rangen water rights is the Martin-Curren Tunnel and does not include

EXHIBIT "504"
Page No. 21 of 81

001968

the spring sources below the tunnel. He concludes that it is not clear that Rangen can demand curtailment to satisfy deliveries associated with the springs below the tunnel.

Sullivan (2012) evaluates fish production data and concludes that the number of fish raised at the Rangen Hatchery is limited by density and flow indices in Rangen's contracts with Idaho Power. Mr. Sullivan suggests that Rangen could increase flow to their upper, small raceways by pumping water from above their lower diversion structure.

Mr. Sullivan identifies City of Pocatello water rights junior to July 13, 1962 that are within the current area of common groundwater supply and analyzes the effect of curtailment of these water rights on Rangen spring complex discharge using ESPAM2.1 response functions. His analysis indicates that the steady state response to curtailment of approximately 3,200 AF/yr would be 13.7 AF/yr (0.019 cfs) at the Rangen spring cell.

IDWR staff comments regarding expert reports

IDWR staff comments regarding expert reports submitted on behalf of Rangen

On page 5, Brockway et al. (2012) state, "*USGS records for Curren Tunnel indicate 50 cfs in 1902 and 96 cfs in 1917*", citing Nace et al. (1958) as a reference. IDWR staff disagrees with this statement. Published records referenced by Nace suggest that these are measurements of the flow in Billingsley Creek and may include discharge from other springs tributary to Billingsley Creek downstream from Curren Spring. Published records do not suggest these records represent the discharge from Curren Tunnel as stated by Brockway et al. (2012).

Nace et al. (1958) provided a compilation of historic spring measurements published by the USGS and the State of Idaho. In April 1902, J.D. Stannard measured and estimated seepage at 119 locations along the Snake River for the Idaho State Engineer. These measurements were first published by Ross (1902) and were referenced by Nace et al. (1958). In April 1902, Mr. Stannard measured 54.4 cfs in Billingsley Creek at a location described as "*4 miles below Salmon Falls*". Nace et al. (1958) states that the location of the measured section is not accurately determinable. In IDWR's opinion, it cannot be conclusively determined from the published information whether this measurement represents the discharge of only the Rangen spring complex, or includes contributions from other springs to Billingsley Creek. Because the Rangen spring complex is located approximately 2.5 miles east-northeast of Upper Salmon Falls and the mouth of Billingsley Creek is about 4.5 miles south of Upper Salmon Falls, it seems more likely that Stannard's measurement includes discharge from the Rangen spring complex and other springs tributary to Billingsley Creek.

The location of the 1917 measurement cited by Brockway et al. (2012) is also uncertain. Nace et al. (1958) cite USGS (1921), Meinzer (1927), and Stearns et al. (1938) as references for a 91.8 cfs measurement in September 1917. These three sources describe a measurement of Kearns Springs located in Section 36, Township 7 South, Range 13 East by the Twin Falls North Side Land and Water

EXHIBIT "504"
Page No. 22 of 81

Company. Nace et al. (1958) state that Kearns was probably a misunderstanding of a vocal reference to Curran Spring and believe this measurement likely applies to Curran Spring. However, IDWR staff note the location described by USGS (1921), Meinzer (1927), and Stearns et al. (1938) is consistent with Billingsley Creek near the Vader Grade road, and the measurement may or may not include discharge from Spring Creek Spring.

On page 14, Brockway et al. (2012) state, "*ESPAM2.1 utilizes the MODFLOW Drain Package to represent 90 spring discharges from the aquifer*…" IDWR staff note that although ESPAM2.1 has 90 drains, many of the spring discharge targets used in model calibration are represented by two, three, or four drains located in one or two model cells. ESPAM2.1 represents spring discharge at 50 spring complexes or groups of springs. Fourteen of these had transient calibration targets (Group A & B springs), and 36 had a single, average calibration target. Individual drains do not explicitly represent a particular discharge point within a given spring complex.

On pages 21-23, Brockway et al. (2012) present results from a steady state ESPAM2.1 simulation of curtailment of groundwater irrigation within the model boundary junior to July 13, 1962. Their analysis predicts a benefit of 17.9 cfs at the Rangen spring complex. Their report states that curtailment results in "*a decrease in ESPA depletion of 1,456,405 acre feet per year*," but their model files indicate that the modeled stress was actually 1.24 MAF/year. This may be the result of misinterpreting the MKMOD output table values for "*total pumping*", which includes water that seeps back into the ESPA and is not equal to the net stress. The net stress is equal to the crop irrigation requirement, which is listed in the MKMOD output table as "*CIR*".

IDWR staff performed a steady state model simulation of the same curtailment to verify the results presented by Brockway et al. (2012). The IDWR analysis was performed using methodology described in Sukow (2012a, 2012b). IDWR's analysis predicts that curtailment within the model boundary will result in a 1.24 MAF/year reduction in depletions to the ESPA, while curtailing irrigation on approximately 565,000 acres. At steady state, this will result in a corresponding increase in gains to the Snake River and springs of 1,705 cfs, with 416 cfs predicted to accrue to springs and reach gains below Milner, 242 cfs predicted to accrue to the Buhl to Lower Salmon Falls reach, and 17.9 cfs predicted to accrue at the Rangen spring complex. IDWR's results are consistent with those presented in Dr. Brockway's Table 2, except for the totals presented at the bottom of his table, which are not consistent with his model files. Results of IDWR's analysis are provided in Attachment A.

It should be noted that the curtailment analysis performed by Brockway et al. (2012) includes curtailment in areas currently outside the area of common groundwater supply as defined by IDAPA 37.03.11.050. If the curtailment simulation is limited to the current area of common groundwater supply, curtailment is reduced to approximately 479,000 acres and the reduction in depletions to the ESPA is 1.09 MAF/year. At steady state, this will result in a corresponding increase in gains to the Snake River and springs of 1,509 cfs, with 392 cfs predicted to accrue to springs and reach gains below Milner, 229 cfs predicted to accrue to the Buhl to Lower Salmon Falls reach, and 16.9 cfs predicted to accrue at Rangen Spring. Results of IDWR's analysis are provided in Attachment A.

EXHIBIT "504"
Page No. 23 of 81

On pages 25-26 and in Appendix C, Brockway et al. (2012) discuss the development of relationships between groundwater levels and discharge at the Rangen spring complex as an alternative method. Dr. Brockway states that regression analyses indicate that over 88% of the variability in Rangen spring discharge can be explained by the water level variability in a predictor well. IDWR staff note that this approach generally appears to be valid, but that use of ESPAM2.1 or another method would still be required to predict the change in water level in the predictor well in response to curtailment.

IDWR staff agree with Brockway et al. (2012) that ESPAM2.1 is the best available science for predicting the response at Rangen Spring to curtailment of groundwater irrigation on the Eastern Snake Plain. IDWR staff also agree that measures of specific components of model uncertainty (uncertainty in model input data, uncertainty in measured observations used as calibration targets, uncertainty in calibrated aquifer parameters) are not equivalent to the uncertainty of a specific model prediction. Predictive uncertainty, as shown in Wylie (2012a), varies with the locations of stresses and responses and cannot be assigned a single numeric value. Regardless of the numeric value of uncertainty, the ESPAM2.1 prediction is currently the best available and most unbiased prediction.

IDWR staff comments regarding expert reports submitted on behalf of IGWA

On page 22 and Figure 12, Mr. Hinckley discusses a schematic MODFLOW model comparison developed by AMEC that is intended to illustrate the potential increase in discharge resulting from construction of Curren Tunnel. IDWR staff note that this model assumes there are no outlets for spring discharge other than the tunnel and thus does not illustrate the potential increase in total discharge to the Rangen spring complex. The lack of an alternative outlet for groundwater in the AMEC model is acknowledged by Mr. Hinckley on page 22.

On page 22, Hinckley (2012) states, "*The outlet elevation of Curren Tunnel has been variously reported as 3138 ft. (Covington and Weaver, 1990), 3145 ft. (Farmer, 2009) and 3150 ft. (IDWR, 2011).*" IDWR staff disagree with part of this statement. Covington and Weaver (1990) mapped "*Rangen Spring*" emerging from Malad Basalt pillow lava facies at an elevation of 3,138 feet, but did not suggest that this elevation represented the tunnel.

On page 24, Hinckley (2012) states, "*Farmer (2009) also rejects a multiple-pathways-through-the-talus interpretation…*" IDWR staff note that Farmer (2009) stated, "*One theory posed is that the actual spring discharge elevation from in-situ geology may be higher than where the spring is visible on the slope due the concept of water flowing out of the in-situ layer (buried beneath the slope material) and then flowing downward through talus and overburden slopes vertically in the subsurface, then flowing laterally again to where it daylights or is visible on the hillside. In my opinion, this phenomenon doesn't occur at Rangen or other springs north of Rangen up to Malad Gorge to as great of a degree as other upriver springs such as Crystal or Clear Springs because of the presence of the GFF in this reach and less overburden and talus*." Mr. Farmer did not reject the possibility of discharge pathways through the talus. He stated that he believes it is not as significant at Rangen spring as at Crystal or Clear Springs. IDWR staff agree that Mr. Farmer identifies two discrete geologic contacts that may control a substantial portion of the discharge to the Rangen spring complex (see Figure 24 in Farmer, 2009), but IDWR staff note that this is

EXHIBIT "504"
Page No. 24 of 81

001971

a conceptual model that is intended to describe apparent major pathways for spring discharge, not all potential pathways for discharge.

On pages 26-27 and Figure 16, Hinckley (2012) criticizes the groundwater elevation contours published in Farmer and Blew (2012), and provides an alternative interpretation of groundwater elevation contours in an approximately 3.5 square mile area adjacent to the Rangen spring complex. The Farmer and Blew (2012) elevation contours were compiled based on water levels measured in 196 wells and 39 springs during November 2011. Mr. Hinckley contoured groundwater elevations in a smaller area based on 18 water level measurements. Mr. Hinckley removed three measurements from the Farmer and Blew dataset and added three measurements taken during different time periods. The measurements collected by Mr. Hinckley included a measurement from November 2007, from well T7S R14E 28DCB1. Measurements collected from the same well in October 2008 and February 2010 indicate water levels 9 to 12.5 feet lower than the November 2007 measurement selected by Mr. Hinckley. IDWR staff disagree with Mr. Hinckley's use of any measurements from well T7S R14E 28DCB1, because none of the measurements are representative of conditions during the November 2011 mass measurement.

Farmer and Blew (2012) contoured groundwater elevations with Surfer software using the Kriging option. This procedure has the advantage of being objective, and does not represent details that are not explicitly defined by the available data. Mr. Hinckley appears to have contoured groundwater elevations using Kriging, then manually adjusted some of the contours based on professional judgement and his interpretation of local conditions. This procedure has the advantage of incorporating geologic knowledge, but also has the disadvantage of incorporating bias based on interpretations that may not accurately reflect the complexity of local conditions. For example, Mr. Hinckley argues on page 26, "*the contouring* [of Farmer and Blew, 2012] *includes a closed contour approximately 1 mile northeast of Rangen. This represents a depression in the potentiometric surface, an unlikely occurrence in a prolific aquifer outside the active irrigation season*." IDWR staff note that the November 2011 synoptic measurement occurred shortly after the end of the irrigation season and that residual transient effects of irrigation well pumping and recharge from surface water irrigation activities may still have resulted in local water level variations, such as depressions or mounds in the potentiometric surface.

On page 27, Mr. Hinckley concludes based on his Figure 16, "*A groundwater divide to the south distinguishes the local Rangen system from the Thousand Springs area. A groundwater divide to the north distinguishes the local Rangen system from rim springs between Rangen and the Malad River*." IDWR staff are unclear what Mr. Hinckley means by "*distinguishes from*" or why Mr. Hinckley believes the existence of these local groundwater divides is significant. Groundwater divides are relevant in controlling contaminant transport, but do not result in hydraulic disconnection nor prevent responses to aquifer stress such as recharge or pumping. Well pumping results in drawdown that propagates radially in all directions (Figure 3). In a finite aquifer without unlimited recharge, drawdown will occur throughout the aquifer. The reduction in aquifer head will be largest near the well and may be very small in distant parts of the aquifer. A groundwater divide is not a hydraulic disconnection, unless caused by a continuous impermeable barrier. A stress applied on one side of a groundwater divide will affect aquifer heads on the other side of the divide and may affect the presence or location of a groundwater divide, which may change seasonally with changes in aquifer stresses. While Hinckley

EXHIBIT "504"
Page No. 25 of 81

001972

(2012) and Farmer and Blew (2012) provide different interpretations of head contours in this area, the presence or absence of these groundwater divides is not relevant to the hydraulic connectivity of the Rangen spring complex to the larger ESPA. As shown in Hinckley (2012) Figure 7, the area contoured in his Figure 16 extends less than two miles from the rim. The extent of the groundwater divides shown by Mr. Hinckley is small relative to the area contoured by Farmer and Blew (2012). Regardless of the precise details of preferred flow pathways and direction in the immediate vicinity of the rim, spring discharge responds to head in the aquifer, and head in the aquifer responds to stresses applied throughout the aquifer.

On page 27, Hinckley (2012) states, "*Groundwater gradients also determine the discharge rates of springs and drainage tunnels. Given an opportunity for discharge, discharge rate is a function of the gradient*." IDWR staff note that this is only partially true, the discharge rate is the product of the gradient and the conductance of the feature (spring or tunnel) at which the discharge occurs. A site with a low gradient may have high discharge if conductance is high, conversely a site with a high gradient may have low discharge if conductance is low. Because spring conductance is a lumped parameter that incorporates all of the head loss between the drain and the point where aquifer head is known or modeled, values for conductance vary over a large range. Conductance depends on the characteristics of the convergent flow pattern toward the drain, as well as on the characteristics of the drain and its immediate environment (Harbaugh, 2005; McDonald and Harbaugh, 1988). Conductance may be influenced by flow turbulence, the size of the drain feature, the size and interconnectivity of fractures or pore spaces, and other physical properties that are difficult or impossible to measure. Because of the number of factors that influence conductance, and the large natural variability in each of these factors, the large range in drain conductance modeled by ESPAM2.1 is realistic.

On page 27 and Figure 17, Hinckley (2012) presents the relationship between discharge of the Rangen spring complex and groundwater level measurements collected in a domestic well (07S 14E33 BBB1) located approximately one mile east-northeast of the Rangen spring complex. Water level measurements from this well were collected approximately bi-monthly by the USGS from 1985 to 2009, and by IDWR beginning in 2009. Mr. Hinckley asserts there is considerable uncertainty in the relationship between aquifer head and spring discharge. IDWR staff disagree, because Mr. Hinckley is not comparing spring discharge with aquifer head immediately adjacent to the spring complex his analysis ignores other factors, such as localized water level responses to nearby pumping wells or recharge sources, potential measurement error in both water level and spring discharge, and transient timing of responses to stress. Figure 4 shows a time-series graph of water level in well 07S 14E BBB1 and discharge at the Rangen spring complex. Figure 5 shows a graph of the relationship between measured water level and spring discharge. Note that much of the scatter discussed by Mr. Hinckley is associated with points in Figure 5 that appear to be outliers occurring when water levels above 3,166 feet were measured in mid-summer. These spikes in the water level measurements suggest that the well is responding to changes in nearby stresses. Changes in aquifer head immediately adjacent to the spring complex will be a function of the transient response time to these and other aquifer stresses.

On page 28 and Figure 18, Hinckley (2012) presents the relationship between discharge of the Curren Tunnel and groundwater level measurements collected in a monitoring well located approximately 600

EXHIBIT "504"
Page No. 26 of 81

001973

feet east of the Rangen spring complex. The monitoring well was installed by the Idaho Water Resource Board (IWRB) in 2008, and daily water level measurements were collected by IDWR beginning in October 2009. In Figure 18, Mr. Hinkley compares daily measurements of water level and Curren Tunnel discharge. Mr. Hinkley asserts that this relationship indicates there is considerable uncertainty in the relationship between aquifer head and Curren Tunnel discharge, again ignoring potential measurement error and transient timing of spring responses to aquifer stresses. Further, linear regression of this relationship (Figure 6) indicates that 85% of the variability in the tunnel discharge during this 3-year period can be explained by a linear relationship with head in the monitoring well (Figure 5). Because the monitoring well was not installed until 2008, these data do not provide sufficient information to evaluate the response to water level changes that would be expected to occur if the aquifer water budget was changed by a model-wide curtailment of groundwater irrigation junior to 1962.

A more representative comparison of aquifer head and Rangen spring complex discharge would be comparison with IDWR Well No. 989, which is located approximately ½ mile northeast of the Rangen spring complex. This well is closer to the Rangen spring complex than well 07S 14E 33 BBB1 and has a longer record of water level measurements than the IWRB monitoring well. Well No. 989 has a record of 68 water level measurements collected between March 1998 and October 2008, representing a broader range of aquifer water budget conditions than the IWRB monitoring well. Well No. 989 was also used as a water level change calibration target in ESPAM2.1 (Figure 7). Comparison of measured water levels with spring discharge indicates that linear regression explains approximately 91% of the variability in the relationship between aquifer head at this location and discharge at the Rangen spring (Figure 8). These data indicate that there is a strong relationship between the change in discharge at the Rangen spring complex and change in aquifer head at the location of Well No. 989, with the discharge increasing by approximately 3.7 cfs per foot of increase in head.

EXHIBIT "504"
Page No. 27 of 81

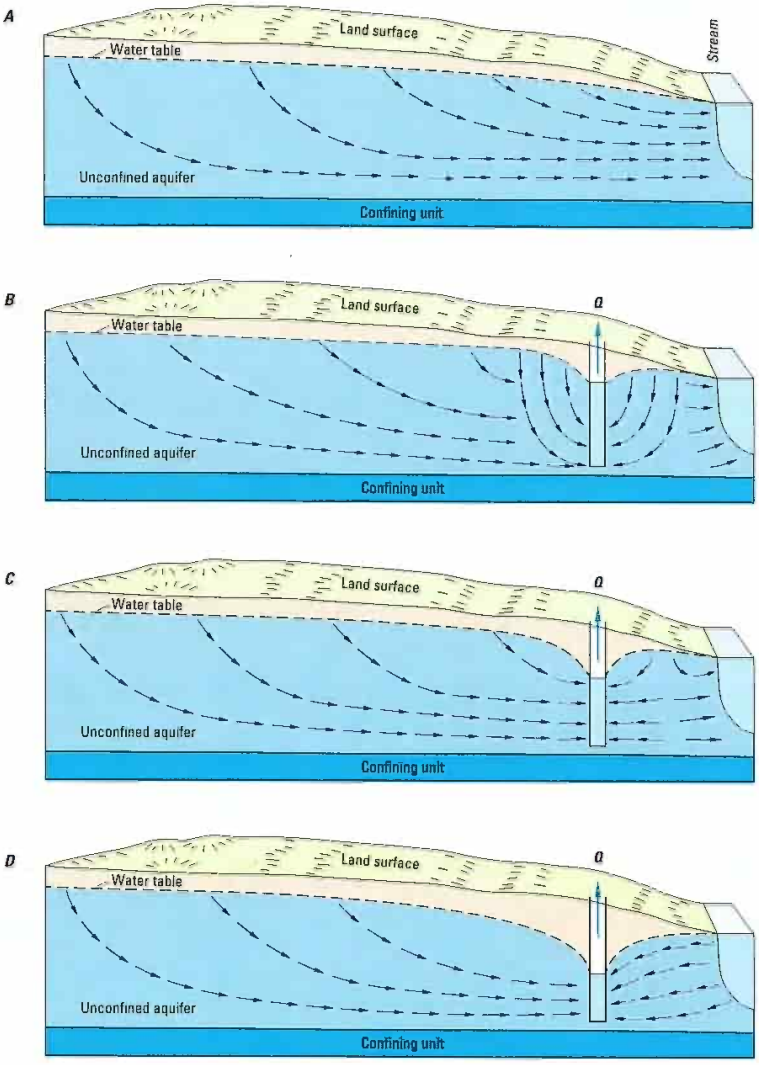

Figure 7. Effects of pumping from a hypothetical water-table aquifer that discharges to a stream. *A*, Under natural conditions, recharge at the water table is equal to discharge at the stream. *B*, Soon after pumping begins, all of the water pumped by the well is derived from water released from groundwater storage. *C*, As the cone of depression expands outward from the well, the well begins to capture groundwater that would otherwise have discharged to the stream. *D*, In some circumstances, the pumping rate of the well may be large enough to cause water to flow from the stream to the aquifer, a process called induced infiltration of streamflow. Streamflow depletion is equal to the sum of captured groundwater discharge and induced infiltration (modified from Heath, 1983; Alley and others, 1999). [*Q*, pumping rate at well]

Page No. 30 of 81

001977

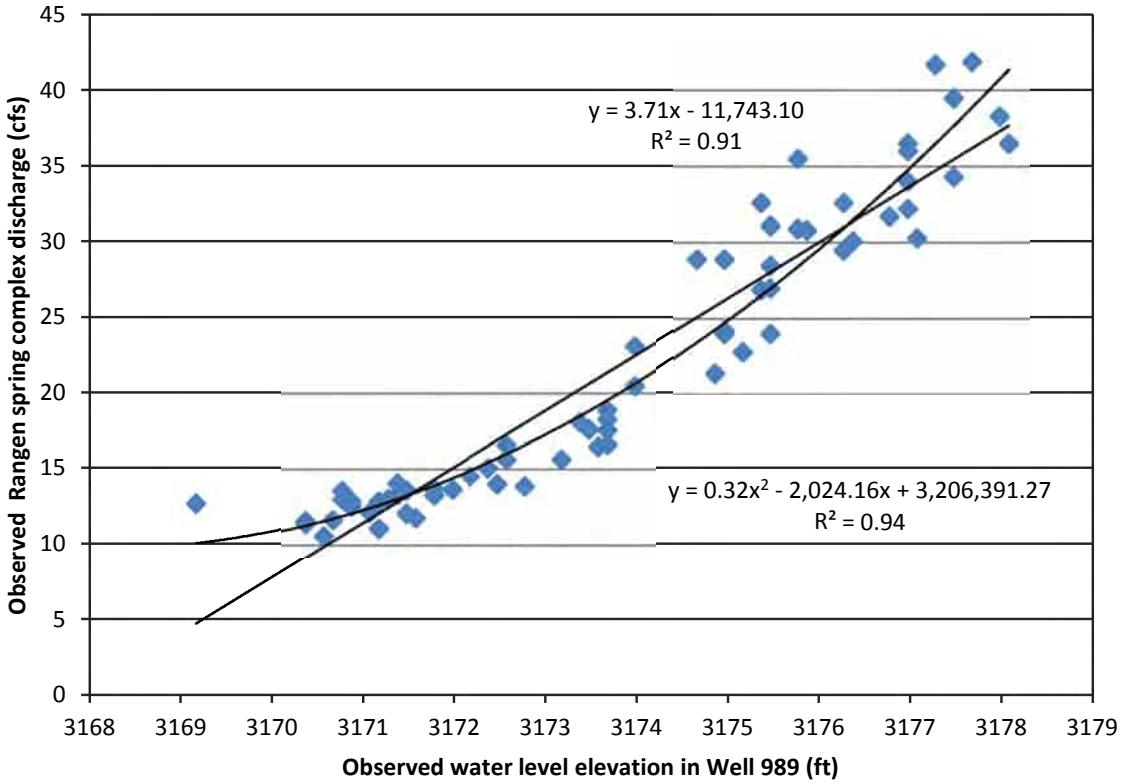

Figure 8. Relationship between Rangen spring complex discharge and aquifer head at IDWR Well No. 989.

On pages 30-45, Mr. Hinckley evaluates the ESPAM2.1 representation of the area between Thousand Springs and Malad. IDWR staff agree with some of Mr. Hinkley's points, but disagree with his conclusion that ESPAM2.1 cannot provide a reasonable prediction of the response at the Rangen spring cell to groundwater pumping in the ESPA. Because ESPAM2.1 is discretized into one-square-mile grid cells, it does not represent detailed topographic and geologic features that are smaller than one-mile in scale. However, ESPAM2.1 does represent regional topography and hydrogeologic features within the constraints of the one-square-mile model grid and the spacing of transmissivity pilot points, which is generally two to four miles in the vicinity of the Buhl to Lower Salmon Falls reach. This provides a better representation of the spatial and hydrogeologic relationships than is available in any other predictive model or method available for evaluating the effects of groundwater pumping within the ESPA on spring and river flows. On a local scale it is not possible to model the complexity of the aquifer with one-square-mile grid cells, however, on a regional scale, the response of head-dependent discharges to springs and rivers is dependent on aquifer head responses to recharge and well withdrawals. This allows responses to regional-scale stresses, such as groundwater pumping throughout the plain to be modeled with less uncertainty than responses to stresses applied in a small area located immediately adjacent to the spring or river.

EXHIBIT "504"
Page No. 31 of 81

001978

IDWR staff agree with Mr. Hinckley that ESPAM2.1 is a linear approximation of a non-linear system, and does not reflect non-linear relationships between aquifer head and spring discharge. IDWR staff note that comparison of aquifer head and discharge (Figures 6 and 8) indicate that a linear regression does provide a reasonable approximation of the relationship, explaining 85 to 91% of the variability in these examples. Non-linear, polynomial regressions of these data only improve this correlation slightly, explaining only an additional 3% of the variability.

As stated by Mr. Hinckley, the model does not allow transmissivity to vary with time. Time-constant transmissivity models of unconfined systems are common in practice, because calibrating models with variable transmissivity is generally not feasible with automated parameter adjustment. Although IDWR staff agree that ESPAM2.1 is a linear approximation of a non-linear system and that this contributes to model uncertainty, IDWR staff do not agree with Mr. Hinckley's conclusion that ESPAM2.1 is not suitable for evaluating the response to aquifer stresses at the Rangen spring cell. ESPAM2.1 is the best available scientific tool for predicting responses to curtailment of groundwater pumping or other changes in regional aquifer stresses within the ESPA. The model was calibrated to spring and river responses to a range of aquifer stresses applied over a 23.5-year period, with net aquifer recharge ranging from 3.2 MAF/year to 6.3 MAF/year and measured discharge at the Rangen spring complex ranging from 11 to 58 cfs. The model calibration targets reflect geologic controls on hydrologic responses to a range of aquifer stresses. ESPAM2.1 provided reasonable approximations of measured discharge at the Rangen spring complex within this range of stresses and responses, and is expected to provide a reasonable approximation of the response to curtailment, which falls within the range of the calibration data set.

On pages 40-41, Hinckley argues, "*ESPAM2.1 is structurally incapable of modeling the relationships shown on Figures 17 and 18. Figure 28, for example, presents the data of Figure 18, expressed as deviations from an ideal linear model as required by ESPAM2.1. The average error in the predicted discharge is 20% of the average discharge, and deviations as large as 50% are not uncommon. Because Figure 28 uses well-measured, paired daily data (e.g. rather than monthly averages), and because the monitor well and discharge points are in near proximity, the relationship presented should be well controlled with respect to data-collection and location based errors.*" IDWR staff disagrees with these statements. The IWRB well referred to by Mr. Hinckley in Figure 28 is located approximately 600 feet from the Rangen spring complex. His comparison of paired daily data ignores transient timing of spring responses to changes in aquifer head, magnifies the impact of measurement error, and results in overestimation of deviations from a linear relationship. Because ESPAM2.1 calculates discharge at the Rangen spring complex to aquifer head at the Rangen spring complex, it is not appropriate to quantify deviations from linearity based on comparisons with aquifer head at a well any distance from the spring complex. As shown in Figure 6, a linear relationship explains approximately 85% of the variability between Curren Tunnel discharge and aquifer head at the IWRB well. Transient response time, measurement error, and physical non-linearity are factors in the other 15% of the variability. It is not appropriate for Mr. Hinckley to attribute all of the variability to physical non-linearity.

On page 42, Hinckley (2012) argues that the use of general head boundaries along the Hagerman rim effectively reverses the removal of the Hagerman Valley from the ESPAM2.1 model domain. IDWR staff disagree with this statement. The general head boundaries were added along the Hagerman rim to

EXHIBIT "504"
Page No. 32 of 81

001979

allow discharge from the ESPA to Billingsley Creek and/or the Snake River via one of several pathways that may include talus flow that does not daylight as spring discharge, discharge from the ESPA to Tertiary sediments to Billingsley Creek, or discharge from the ESPA to Tertiary basalts to the Snake River as conceptualized by Farmer, 2009 (Figure 9). The general head boundaries were added to provide an outlet for ESPA discharge that reaches Billingsley Creek or the Snake River without surfacing as springs. This does not reverse the removal of the Hagerman Valley from the ESPAM2.1 model domain, because there is no modeled aquifer recharge or discharge occurring in the Hagerman Valley, and elevations of the general head boundary were selected to be low enough that there was not any flux modeled from the Snake River into the ESPA in the reaches below Milner.

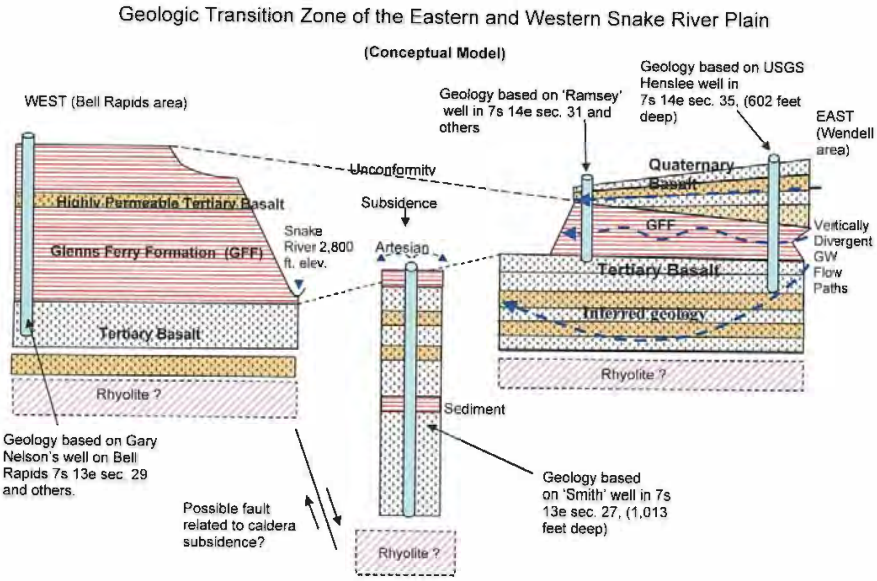

Figure 20. Conceptual model of Hagerman Valley (not to scale).

Figure 9. Farmer (2009) conceptualization of potential groundwater flow from ESPA to Tertiary sediments and basalts.

EXHIBIT "504"
Page No. 33 of 81

The locations of general head boundaries used to model base flow below Milner were discussed by the ESHMC, including Dr. Brendecke on December 12, 2011 and the committee agreed that a general head boundary "*would be assigned to cells with springs that butt against the river, and for cells along the edge of the Hagerman Valley*" (Raymondi, 2011). IDWR staff note that the analyses submitted by Leonard Rice Engineers, Inc. with Rangen's December 13, 2011 Petition for Delivery Call was performed using a preliminary calibration of ESPAM2 that pre-dated addition of the general head boundaries to the model. The results of their analysis (McGrane, et al., 2011) were similar to the results predicted by ESPAM2.1, suggesting that the addition of the general head boundaries along the Hagerman rim had little effect on model predictions of response at the Rangen spring complex.

On page 43, Hinckley (2012) claims that the ESPAM2.1 calibration targets for the general head boundary base flow were "*a constant, average value…despite the fact that the total gains through this reach have declined over the period, and include seasonal fluctuations of 700 cfs.*" This claim is false. In ESPAM2.1, each base flow reach was calibrated to an average value for the calibration period, not a constant value. During calibration, the average of model-calculated discharge from May 1985 through October 2008 was computed and compared to the target average value from Wylie (2012b). The model calibration is only constrained by the average value for the calibration period, and is still allowed to vary the base flow discharge with time to match fluctuations in the transient reach gain targets.

Brendecke (2012) concludes that observed flows of Billingsley Creek have not been high enough to provide any water to water right 36-7964 since October 1976, a date which precedes the water right's 4/12/1977 priority date. This is consistent with IDWR's previous review of this water right. Dreher (2005), stated "…*Rangen may be entitled to divert water under this right when such water is physically available. However, because water was not available to appropriate on the date of appropriation for right no. 36-07694, Rangen may not be entitled to have a delivery call recognized against junior priority rights*." From a practical standpoint this is not relevant, because the predicted benefit from curtailing all groundwater users junior to the 7/13/1962 priority date of water right 36-2551 is only 17.9 cfs, and curtailment is not expected to provide more water than Rangen is entitled to divert under water right 36-2551. Between 2002 and 2011, annual average spring discharge ranged from 12 to 16 cfs, and monthly average spring discharge ranged from 11 to 22 cfs (Sullivan, 2012, Table 2-2). Based on 2002 to 2011 conditions, the predicted total annual average spring discharge would be between 30 and 34 cfs with curtailment.

Brendecke (2012) concludes that the source for water right 36-2551 is the Martin-Curren Tunnel and that flows from the tunnel have never been high enough to deliver the maximum diversion rate authorized under water right 36-2551. IDWR staff agree that the SRBA partial decree for water right 36-2551 lists the source as Martin-Curren Tunnel and describes the 10-acre tract containing the tunnel. A cursory review of the water right file indicates that the water right was licensed with the source described as "*underground springs tributary to Billingsley Creek*" and the point of diversion is located in the 40-acre tract containing both Curren Tunnel and Rangen's diversion at the head of the creek. The water right file also contains two survey drawings showing the point of diversion from the creek and the 36-inch pipe to the large raceways. The licensed priority date was July 31, 1962. The files reviewed did not indicate why the source, point of diversion, and priority date were changed in the SRBA.

EXHIBIT "504"
Page No. 34 of 81

001981

Brendecke (2012) concludes that the Martin-Curren Tunnel meets the physical definition of a well contained in Idaho Code 42-230(b), which states, *"'Well' is an artificial excavation or opening in the ground more than eighteen (18) feet in vertical depth below land surface by which ground water of any temperature is sought or obtained*." The partial decree lists the source for water right 36-2551 as "*Martin-Curren Tunnel*", not "*Ground Water*". Whether the tunnel is considered a well or a developed spring for administration of water right 36-2551 is a legal, not a technical, question.

Brendecke (2012) concludes that much of the change in spring discharge in the Milner to King Hill reach since 1960 can be attributed to reduction in incidental recharge from surface water irrigation. IDWR staff acknowledge that reduction in incidental recharge from surface water irrigation has contributed significantly to reductions in spring discharge. Spring flows respond to changes in various types of aquifer stress, including changes in incidental recharge from surface water irrigation, well pumping, and infiltration of precipitation. ESPAM2.1 was calibrated with all of these stresses, and then the calibrated model was used to calculate the response to a change in well pumping while other stresses were held constant. ESPAM2.1 provides a method for determining the portion of the water shortage at the Rangen hatchery that can be attributed to junior groundwater pumping, rather than holding junior groundwater users accountable for the entire decrease in spring discharge. Spring discharge records indicate that the annual average spring discharge was 51 cfs in 1966 and 14 cfs in 2008 (Sullivan, 2012, Table 2-2). The steady state impact of junior groundwater pumping predicted by ESPAM2.1 is less than half of the total decrease in spring discharge between 1966 and 2008. Note that spring discharge in 1966 would have already been reduced to some extent by junior groundwater pumping developed between 1962 (the priority date for water right 36-2551) and 1966.

Brendecke (2012) states that "*The 1992 moratorium on new irrigation wells suggests that decreases in discharge after the mid-1990s are not the result of groundwater pumping*." IDWR staff note that groundwater pumping junior to July 13, 1962 has resulted in depletions to spring discharge every year since 1962. While the rate of depletion due to groundwater pumping may not have increased significantly since 1992, the depletions continue to occur. These depletions are superimposed on decreases in spring discharge resulting from changes in surface water irrigation practices and natural recharge derived from precipitation. Even if the rate of depletion due to groundwater pumping has been approximately constant since 1992, groundwater pumping continues to contribute to removal of water from aquifer storage, declines in ESPA water levels, and decreases in spring discharge.

Brendecke (2012) mentions that former Director Dreher found that curtailment of water rights junior to July 13, 1962 would not result in a meaningful increase in the quantity of water discharge from springs in the Thousand Springs to Malad Gorge spring reach, which includes the Curran Spring from which Rangen diverts surface water. Dreher (2005) indicates that this conclusion was based on simulations using ESPAM1.1. During development of ESPAM2.1, IDWR discovered that values from Covington and Weaver (1990) that were used to estimate discharge for Thousand Springs and springs in the Thousand Springs to Malad spring reach for calibration of ESPAM1.1 were inaccurate. These values were corrected in the calibration targets used for ESPAM2.1. These corrections included a significant decrease in the spring discharge target at Thousand Springs and a significant increase in spring discharge targets in the Billingsley Creek area (Table 2). ESPAM2.1 calibration targets also provided the model

EXHIBIT "504"
Page No. 35 of 81

001982

with information regarding transient changes in spring discharge in the Billingsley Creek area. Because ESPAM2.1 incorporates these and other improvements to ESPAM1.1, ESPAM2.1 model predictions are an improvement to analyses performed using ESPAM1.1.

ESPAM1.1 Spring Reach	ESPAM1.1 Discharge Target (cfs)	ESPAM1.1 Proportion of Milner to King Hill Discharge	Sum of Average ESPAM2.1 Discharge Targets (cfs)	ESPAM2.1 Proportion of Milner to King Hill Discharge
Devil's Washbowl to Buhl	1,002	0.18	840	0.14
Buhl to Thousand Springs	1,584	0.28	1,431	0.24
Thousand Springs	1,749	0.31	811	0.13
Thousand Springs to Malad (Billingsley Creek)	77	0.01	223	0.04
Malad	1,117	0.20	1,070	0.18
Malad to Bancroft	91	0.02	103	0.02

Sum	5,620	1.00	6,015	1.00

Table 2. Comparison of calibration targets for springs below Milner.

Brendecke (2012) mentions that approximately 24,000 linear feet of lateral off the W-Canal in the area west of Wendell have been lined or placed in pipe since the 1990s, reducing incidental recharge. IDWR staff note that ESPAM2.1 does model this reduction in incidental recharge, because the sum of incidental recharge and canal seepage in the North Side Canal Company service area is equal to recorded diversions less crop irrigation requirement and return flow. IDWR staff also acknowledge that, while the volume of recharge reflects the canal lining/piping projects, the spatial distribution of the recharge does not reflect this change. The pre-processing tools developed for use with ESPAM2.1 have the ability to reflect changes in canal seepage rates with time, and this improvement could likely be incorporated into future versions of ESPAM2 if proposed to the ESHMC for consideration.

On page 4-4 Brendecke (2012) states that in ESPAM2.1 "*canal seepage losses are still considered to be constant throughout the model study period*." IDWR staff would like to clarify that canal seepage rates in ESPAM2.1 were calculated as a constant percentage of diversions. Canal seepage losses vary with time, because diversions vary with time.

EXHIBIT "504"
Page No. 36 of 81

001983

On page 4-6, Brendecke (2012) states that the number of adjustable parameters in ESPAM2.1 model calibration increases the likelihood that the model is not linear. Dr. Brendecke appears to misinterpret a quote from Doherty (2005). This quote refers to the linearity of the model calibration process, not the linearity of the calibrated MODFLOW model. IDWR addressed the non-linearity of the calibrated MODFLOW model in Sukow (2012c) with respect to the use of superposition to perform curtailment simulations.

On page 4-9, Brendecke (2012) states that water levels in the ESPA near Rangen vary seasonally by about 5 feet and that "*These changes are nearly 100% of the saturated thickness above the Tunnel and about 10% of the thickness above the lower springs, further indicating that the requirements for superposition are not met at Rangen*." Dr. Brendecke appears to be referring to the guidelines for using a time-constant representation of transmissivity, not requirements for superposition. As stated in the ESPAM2.1 model documentation (IDWR, 2013), "*The generally considerable saturated thickness of the ESPA supports a time-constant representation of transmissivity, because drawdown is generally expected to be less than 10% of total saturated thickness (Anderson and Woessner, 1992)*." Note that this guideline applies to water level change as a percentage of the total saturated thickness. The portion of the saturated thickness that is above the tunnel elevation is not relevant, because the tunnel is not located at the base of the aquifer. If the lower springs are assumed to be located at the base of the aquifer, the water levels changes would be about 10% of the total saturated thickness, as acknowledged by Dr. Brendecke. Therefore, the conditions described by Dr. Brendecke are at the limit of the standard cited in IDWR (2013), but do not exceed this standard.

Brendecke (2012) indicates that ESPAM2.1 is not capable of separating the effects of groundwater pumping on flows from the Martin-Curren Tunnel from the effects on other springs in the Rangen complex. IDWR staff agree with this statement. Even in other spring cells where ESPAM2.1 has two drains, the model is calibrated to target data that reflect the total flow of all springs in the cell. Apportioning the predicted response between the tunnel and other springs in the Rangen complex, could done by applying a post-model calculation to the model prediction. The methodology should consider the amplitude of observed changes in the tunnel discharge and discharge from other springs, not the average magnitude of the discharges. Observed data (Figure 10) indicate that Curren Tunnel discharge is more responsive than discharge from other springs in the complex to changes in aquifer head. Linear regression of Curren Tunnel discharge with total Rangen spring complex discharge (Figure 11) indicates that the change in discharge at Curren Tunnel will be approximately 70% of the change in total spring complex discharge.

Page No. 38 of 81

001985

Brendecke (2012) and Hinckley (2012) suggest that ESPAM2.1 would better represent the Rangen spring complex if two drains with different elevations were assigned to the model cell. IDWR staff agree that adding a second drain to the model cell would provide PEST with an additional tool and would likely improve the match to the Rangen calibration target. This improvement has been suggested for ESPAM2.2 (for Rangen and several other spring cells), and could likely be incorporated into future versions of ESPAM if proposed to the ESHMC for consideration. Although IDWR staff agree that adding a second drain to the model cell would be appropriate, IDWR staff disagree that the drains could be used to calculate the response at Curren Tunnel separately from other springs in the Rangen complex. In ESPAM2.1, spring cells with two drains are calibrated to a single set of discharge data representing discharge occurring throughout the model cell. The use of two drain cells allows PEST to find an effective elevation (Equation 1) between the upper and lower drain elevation that allows the best linear approximation of the relationship between aquifer head and observed spring discharge. Because the elevation or range of elevations at which the spring discharge loses hydraulic connection with the aquifer are unknown, using two drain elevations provides PEST the opportunity to find the best estimate for the effective elevation (within the assigned range) based on available head and discharge data. Provided aquifer head remains above both drain elevations throughout the simulation period, total drain discharge in the model cell can be represented by Equation 2.

$$z_{eff} = (C_1 z_1 + C_2 z_2)/(C_1 + C_2) \quad \text{(Equation 1)}$$

where:
z_{eff} = effective drain elevation (ft)
C_1 = conductance of upper drain (ft^2/day)
z_1 = elevation of upper drain (ft)
C_2 = conductance of lower drain (ft^2/day)
z_2 = elevation of lower drain (ft)

$$Q_d = C_1(z_1 - h_{aq}) + C_2(z_2 - h_{aq}) = (C_1 + C_2)(z_{eff} - h_{aq}); \text{ if } h_{aq} > z_1 \text{ and } h_{aq} > z_2 \quad \text{(Equation 2)}$$

where:
Q_d = total drain discharge (ft^3/day) in model cell, negative values indicate flux out of the aquifer
h_{aq} = aquifer head at center of cell containing the drain (ft)

Hinckley (2012) and Brendecke (2012) argue that representing the Rangen spring discharge with a single drain at elevation 3,138 feet in ESPAM2.1 resulted in a drain conductance that is unrealistically high. Brendecke (2012) explored the effects of representing the Rangen spring discharge with two drains in his alternative models, AMEC Model 1 and AMEC Model 2. Dr. Brendecke's drain file for AMEC Model 1 show that his model has a drain conductance of 11,307 ft^2/day at an elevation of 3,100 feet and a drain conductance of 363,270 ft^2/day at an elevation of 3,152 feet. In this model, the Rangen spring discharge is represented by an effective conductance of 374,577 ft^2/day at an effective elevation of 3,150.4 feet. AMEC Model 2 has a drain conductance of 23,862 ft^2/day at an elevation of 3,100 feet and a drain conductance of 357,756 ft^2/day at an elevation of 3,148 feet. In this model, the Rangen spring discharge

EXHIBIT "504"
Page No. 39 of 81

001986

is represented by an effective conductance of 381,618 ft^2/day at an effective elevation of 3,145.0 feet. The effective response to a unit change in head in Dr. Brendecke's alternative models is only 9-11% lower than in ESPAM2.1, contradicting Mr. Hinckley and Dr. Brendecke's assumptions that the ESPAM2.1 drain conductance value is unreasonable.

Brendecke (2012) said that the predictive uncertainty analysis of ESPAM2.1 carried out by IDWR explores only a limited aspect of model uncertainty, and that conceptual model uncertainty is fundamental to overall model uncertainty. Dr. Brendecke presents two alternative conceptual models, AMEC Model 1 and AMEC Model 2, which he uses to explore conceptual model uncertainty. Dr. Brendecke asserts that these alternative models better represent local conditions in the vicinity of Rangen through the following modifications to ESPAM2.1:

1. A horizontal flow barrier was added to represent a geologic discontinuity between the Rangen spring complex and the Tucker spring complex.
2. The Rangen spring complex was represented by two drains. The lower drain was assigned an elevation of 3,100 feet in both alternative models. The upper drain was assigned an elevation of 3,152 in AMEC Model 1 and 3,148 feet in AMEC Model 2.
3. General Head Boundaries assigned to four cells along the Hagerman rim were removed.
4. In AMEC Model 2, the calibration weights for Rangen spring discharge observations after the year 2000 were increased to encourage the model to concentrate on matching those observations at the expense of earlier observations.
5. Water level data from an additional well were added to the calibration targets.

IDWR staff note that several of the conceptual model decisions implemented in ESPAM2.1, including the use of a single drain with an elevation based on Covington and Weaver (1990), the assignment of General Head Boundaries to model cells along the Hagerman Rim, and calibration weights were discussed with the ESHMC. Items 2 and 5 could likely be implemented in calibration of future versions of ESPAM if proposed to the ESHMC for consideration. Item 4 is an inappropriate change. Encouraging the model to match observations during a particular time period at the expense of other time periods results in a poorer representation of physical conditions. Items 1 and 3 are based on subjective geologic interpretations that would need to be presented to the ESHMC for review and discussion.

Dr. Brendecke evaluates the calibration quality of his alternative models by comparing the model and observed values for only three calibration targets, the Rangen spring complex discharge and aquifer head elevation in two wells. IDWR staff did not perform an extensive review of the alternative models, but did note that the contributions to the objective function shown in Dr. Brendecke's calibration files indicate both AMEC models had a poorer match to observed discharges at the nearby Three/Weatherby springs complex. These files and Dr. Brendecke's Figure 6.4b indicate that the improved match to the last eight years of observed Rangen complex discharge in AMEC Model 2 was achieved at the expense of the overall match to discharge observed during the other 20 years of the ESPAM2.1 simulation period. The contribution of residuals at the Rangen spring complex to the objective function is approximately 60% larger in AMEC Model 2 than in ESPAM2.1.

EXHIBIT "504"
Page No. 40 of 81

001987

On pages 6-7 and 6-8, Dr. Brendecke explores the conceptual model uncertainty by performing analyses of curtailment of junior groundwater use within an area defined by a 10% trimline using AMEC Model 1 and AMEC Model 2. IDWR staff analyses indicate that Dr. Brendecke overstates the uncertainty illustrated by these alternative models for several reasons:

1. It appears that Dr. Brendecke did not use the correct 10% trimline in his analysis performed with ESPAM2.1. AMEC's model files show that pumping was applied in model cells 1041014 and 1043013, which both have steady state response functions of 9.53% with respect to the Rangen spring complex. IDWR analysis using ESPAM2.1 indicates that the response to curtailment within the 10% trimline, which only consists of four model cells (a four-square-mile area), is negligible (0.01 cfs) because the simulated curtailment volume is negligible.
2. It appears that Dr. Brendecke did not use the correct 10% trimline in his analysis performed with AMEC Model 1. AMEC's model files show that pumping was applied in model cell 1041014, which has a steady state response function of 9.74% in AMEC Model 1.
3. An analysis of model uncertainty should be performed by comparing responses to the same stress. Dr. Brendecke uses a different stress file in each of his three simulations, with total stress applied ranging from 0.1 to 2.0 cfs. This comparison does not illustrate uncertainty in the ESPAM2.1 MODFLOW model; it illustrates uncertainty in delineating the area subject to curtailment. In Dr. Brendecke's example, mistakes in delineating the 10% trimline appear to be the primary source of the uncertainty cited by Dr. Brendecke on pages 6-7 and 6-8.
4. IDWR compared model predictions made by AMEC's alternative models with ESPAM2.1 predictions applying consistent stress files. Table 3 shows the results of these comparisons, which indicate that the predictions made by AMEC's alternative models are very similar to predictions made by ESPAM2.1.

Curtailed area	ESPAM2.1 prediction (cfs)	AMEC Model 1 prediction (cfs)	AMEC Model 2 prediction (cfs)
Model extent	17.9	18.5	18.0
Four cells in ESPAM2.1 10% trimline for Rangen	0.01	0.01	0.01

Table 3. IDWR comparison of predicted responses at the Rangen spring cell to curtailment junior to July 13, 1962 using ESPAM2.1 and AMEC's alternative models.

The results shown in Table 3 indicate that the conceptual model changes implemented by Dr. Brendecke in AMEC Model 1 and AMEC Model 2 did not significantly affect the prediction of responses to curtailment within a given area. For the model extent, the responses predicted by AMEC's alternative models were slightly (0.6% to 3.5%) larger than those predicted by ESPAM2.1. For the area delineated

EXHIBIT "504"
Page No. 41 of 81

by the four cells in the ESPAM2.1 10% trimline for the Rangen spring cell, the response is negligible using all three models.

Brendecke (2012) said that ESPAM2.1 mischaracterizes the physical relationship between water levels and flows at Rangen, resulting in over-sensitivity of the change in drain flow to a simulated change in water level due to curtailment. Dr. Brendecke asserts that changes in spring flows are over-predicted by nearly a factor of 4 (page 1-6 and 4-9). IDWR staff disagree with this conclusion. Dr. Brendecke compares the calibrated drain conductance in ESPAM2.1 with the relationship between the discharge of Curren Tunnel and water level in a monitoring well located about 600 feet east of the Rangen spring complex (Hinckley, 2012, Figure 18). This is not a valid comparison because the ESPAM2.1 drain conductance is calibrated to the total discharge of the Rangen spring complex, not the discharge from Curren Tunnel, and because the data available for the comparison in Hinckley (2012) only represent a limited time period between August 2008 and January 2012. These data do not represent the range of responses included in the calibration data set for ESPAM2.1, which extended from May 1985 to October 2008. Further, simulations performed with Dr. Brendecke's alternative models, which he asserts better characterize the physical relationship between water levels and flows at Rangen, provide similar predictions to ESPAM2.1 (Table 3).

Dr. Brendecke also concludes that the representation of the Rangen spring complex as a single drain with an elevation of 3,138 feet and ESPAM2.1's over-prediction of spring complex discharge in recent years result in over-prediction of responses to curtailment. Dr. Brendecke explored these issues in his alternative models AMEC Model 1 and AMEC Model 2. As shown previously in Table 3, analyses performed using these alternative models predict responses similar to ESPAM2.1. In simulations of curtailment of junior groundwater pumping over the model extent, Dr. Brendecke's alternative models predict slightly larger responses, even in AMEC Model 2, which concentrated on matching Rangen spring discharge observations after the year 2000. These results contradict Dr. Brendecke's conclusion.

Brendecke (2012) compares the area encompassed by a 5% trimline to the Rangen spring complex in ESPAM2.1 to ESPAM2.0, and concludes that the ESPAM2.1 5% trimline has expanded to include areas "*on the opposite side of the Malad Gorge from Rangen, which are hydrogeologically disconnected from Rangen Spring*." IDWR disagrees with Dr. Brendecke's assertion that this is "*evidence of unexpectedly large changes in ESPAM2.1*" for two reasons. First, the changes in the delineation of a 5% trimline are the result of response functions in cells changing from slightly less than 5% (4.822% to 4.997%) in ESPAM2.0 to slightly greater than 5% (5.0004% to 5.118%) in ESPAM2.1. Stresses applied in areas outside the 5% trimline will still result in a response at the Rangen spring complex; the response will be less than 5%, but will not be zero. Second, the area on the opposite side of the Malad Gorge is hydraulically connected to the Rangen spring complex via the ESPA aquifer to the east of Malad Gorge. This is acknowledged by Hinckley (2012), who notes that, "*If the aquifer is severed by the gorge…any impacts to groundwater levels on the north side can only be communicated to the south side via the continuously saturated portions of the primary aquifer further east, or through the lower aquifer*…" IDWR staff analyses also indicate that the predicted response at the Rangen spring complex to curtailment within the area delineated by the ESPAM2.1 5% trimline is 3.35 cfs, nearly identical to the prediction calculated using ESPAM2.0.

EXHIBIT "504"
Page No. 42 of 81

On page 4-11, Brendecke (2012) states that ESPAM2.1 is "*called upon to represent highly localized conditions such as those governing discharge from specific outlets of a specific spring complex*." IDWR staff would like to clarify that ESPAM2.1 does not represent specific spring outlets. In no case does it represent or predict discharge at a scale smaller than a one-square-mile model cell. In the case of the Rangen spring complex, which is the only spring complex in its model cell, ESPAM2.1 is calibrated to the total discharge of the spring complex. It is not calibrated to, and cannot predict discharge from specific outlets within the spring complex.

Brendecke (2012) concludes that ESPAM2.1 is a linear representation of a non-linear physical system. IDWR staff agree with this conclusion and acknowledge that ESPAM2.1, like all models, is an approximation of the physical system. Although there is uncertainty associated with using a model to approximate a physical system, it is the opinion of IDWR staff that ESPAM2.1 is the best available scientific tool for predicting the response at the Rangen spring complex to regional curtailment of groundwater. Based on IDWR's analyses, ESPAM2.1 predicts a response of 17.9 cfs to curtailment within the model boundary, 16.9 cfs to curtailment within the area of common groundwater supply, and 0.01 cfs to curtailment within the area delineated by a 10% response function. While there is uncertainty in these predictions, it is likely that the response to curtailment within the model boundary or the common groundwater area will be a measurable amount of water, and that the response to curtailment in an area delineated by a 10% response function will be a negligible amount of water.

Brendecke (2012) concludes that ESPAM2.1 predicts a benefit of 0.19 cfs will accrue to the Rangen spring complex if a 10% trimline is applied. IDWR analyses indicate that Dr. Brendecke did not use the correct area for the 10% trimline, and that the predicted benefit using ESPAM2.1 is 0.01 cfs if a 10% trimline is applied. Review of Dr. Brendecke's model files also indicates that he applied a stress equal to total pumping, rather than applying a stress equal to the crop irrigation requirement or net pumping. Total pumping includes some water that is pumped from wells, but is returned to the aquifer as recharge. IDWR staff recommend modeling a stress equal to the crop irrigation requirement to represent the long term effects of groundwater use. IDWR staff also note that delineation of a trimline based on response functions for the Rangen spring complex is a direct application of ESPAM2.1-predicted responses at the Rangen spring cell, which Dr. Brendecke argues are unreliable predictions. If, as argued by Dr. Brendecke, ESPAM2.1 "*cannot be relied upon to accurately predict changes in flow at Rangen*" because it is a regional model then it would be more appropriate to use predictions of steady state response functions for the Buhl to Lower Salmon Falls reach, as suggested by Contor (2012a).

On pages 1-2, Table 5.2 and Table 6.1, Brendecke (2012) asserts that less than 3% of the curtailed groundwater rights within a 10% trimline would accrue to the Rangen spring complex. IDWR staff disagree with this statement. By definition, a 10% trimline is the area within which 10% or greater of the effect of an applied stress will accrue to the Rangen spring complex. In Tables 5.2 and 6.1, Dr. Brendecke compares the change in flow at the Rangen complex to a typical maximum water right diversion rate of 0.02 cfs per irrigated acres. The maximum diversion rate is considerably greater than the actual curtailed groundwater use. Dr. Brendecke should have compared the change in flow at the Rangen complex to the curtailed groundwater use in the fourth column of Table 5.2 and fifth column of Table 6.1. The resulting increase as a percentage of the curtailed groundwater use for Dr. Brendecke's

EXHIBIT "504"

001990

simulations is 10.5% for his ESPAM2.1 simulation, 10.8% for his Alternative Model #1 simulation, and 11.6% for his Alternative Model#2 simulation. IDWR's analysis performed using ESPAM2.1 with the correct 10% trimline indicates that the response at Rangen is 12.8% of the curtailed groundwater use.

On page 1-7, Dr. Brendecke quantifies the effects of curtailing all junior groundwater irrigation within the model domain as modeled by ESPAM2.0. Dr. Brendecke provides an incorrect value for the volume of curtailed consumptive use and did not update the results using ESPAM2.1. IDWR's analyses with ESPAM2.1 indicate that there are approximately 565,026 acres within the model domain irrigated with groundwater rights junior to July 13, 1962. The estimated consumptive use (net withdrawal from the aquifer) associated with this irrigation is 1.24 MAF per year. At steady state, ESPAM2.1 predicts curtailment will result in an increase of 17.9 cfs at the Rangen spring complex. The model predicts that it will take approximately 13 years for the response to reach 90% of the steady state increase.

On page 4-10, Brendecke (2012) states that the comparison of ESPAM2.1 with ESPAM1.1 performed by IDWR "*highlights the sensitivity of ESPAM2 results to conditions in particular years*." This is not a valid interpretation of the results. Changes in estimates of irrigated acreage between ESPAM1.1 and 2.1 are the result of improvements in GIS technology and methodology used to delineate irrigated lands, not sensitivity to conditions in particular years. Changes in estimates of crop irrigation requirements result largely from changing from 1971-2000 average precipitation used with ESPAM1.1 to a November 1998 to October 2008 average precipitation with ESPAM2.1. The 1971-2000 period used to estimate precipitation with ESPAM1.1 curtailment simulations resulted in estimates of precipitation higher than the long term average from 1934 through 2008. Average precipitation from the 1998-2008 period used with ESPAM2.1 curtailment simulations is closer to the long term average.

On page 4-13, Brendecke (2012) claims that the IDWR predictive uncertainty analysis "*assumed that pumping stress for entire Water Districts could be applied at the centroids of each District without loss of accuracy*." IDWR staff would like to clarify that IDWR did not make such an assumption. The predictive uncertainty analysis was not intended to model the impacts of Water Districts on spring discharge or reach gains. The centroids of Water Districts were used to select representative points for the analyses that were distributed throughout the model domain in areas where irrigated lands are present.

On page 4-14, Brendecke (2012) states "*While it is clearly an improvement over its predecessor, several important features are the same in ESPAM1.1 and ESPAM2.1. The two are still conceptually the same regional model. Differences between them are largely the result of differences in input data and in values of calibration parameters resulting from use of that input data. Both models represent the details of the Rangen spring complex and the surrounding geology in highly simplified form, omitting several key features that would make significant differences in predicted benefits of curtailment*." IDWR staff note the differences between these models' predictions of response to curtailment at springs tributary to Billingsley Creek are largely the result of the use of calibration targets in ESPAM1.1 that were not representative of discharge at springs tributary to Billingsley Creek and at Thousand Springs. The ESPAM2.1 calibration targets were a significant improvement over ESPAM1.1. ESPAM2.1 was also calibrated with more closely spaced transmissivity pilot points than ESPAM1.1, allowing more local-scale variation in transmissivity than ESPAM1.1. IDWR staff also note that Dr. Brendecke assumes that details

EXHIBIT "504"
Page No. 44 of 81

not included in the ESPAM2.1 representation of the Rangen spring complex and surrounding geology "*would make significant differences in predicted benefits of curtailment*," but does not provide evidence supporting this statement. Dr. Brendecke's exploration of conceptual model uncertainty shows that the predicted benefits of curtailment at Rangen made by his alternative models are less than 3.5% different than the prediction made by ESPAM2.1.

On page 4-14, Brendecke (2012) states that curtailment of large amounts of junior groundwater pumping would results in water use conditions "*that are radically different from those extant in the model calibration period*." IDWR staff disagree with this statement. As shown in Figure 12, when the simulated curtailment volume is added to the 2002-2007 average annual net recharge, the net ESPA recharge is within the range of net recharge during the model calibration period and is closest to conditions that occurred in the late 1990s.

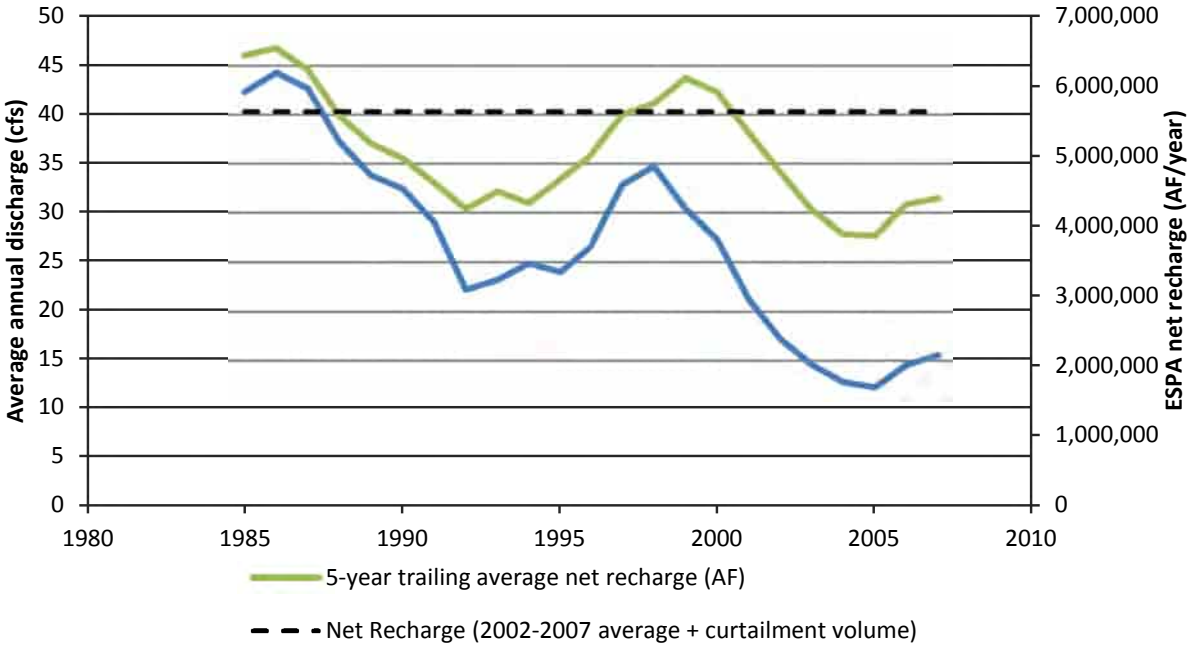

Figure 12. Comparison of net ESPA recharge during model calibration period and simulation of curtailment to July 13, 1962.

On page 5-1, Brendecke (2012) mentions that IDWR provided a superposition version of ESPAM2.1 and states that "*a superposition model can introduce significant error into the analysis of effects of stress changes*." IDWR staff note that the fully populated model files are also available to Dr. Brendecke and

EXHIBIT "504"
Page No. 45 of 81

001992

the public[5]. Dr. Brendecke could have simulated the curtailment using the fully populated version of the model to explore any potential difference in the prediction at the Rangen spring complex. IDWR staff explored the difference between predictions made using fully populated and superposition versions of ESPAM2.0 and found that there was not a significant difference in predicted responses to curtailment at the Rangen spring cell (Sukow, 2012c). Because the model structure and degree of model linearity did not change between ESPAM2.0 and ESPAM2.1, the conclusions of Sukow (2012c) apply to ESPAM2.1. IDWR staff did not perform the curtailment simulation for this water delivery call with the fully populated version, because IDWR staff are confident the predicted response would not be significantly different from the results of the superposition version.

On page 9, Church (2012) states, "*assuming a diversion rate of 0.02 cfs per acre, the curtailment of 479,200 groundwater irrigated acres would immediately eliminate beneficial use of 9,584 cfs. By this comparison, Rangen would receive less than two-tenths of 1% (0.0018) of the curtailed water*." IDWR staff disagree with Mr. Church's assumption that the curtailed use will be 0.02 cfs per acre, because this is the typical maximum authorized diversion rate. Mr. Church assumes that irrigators would be diverting the maximum diversion rate 24 hours per day, 7 days a week, 365 days per year and significantly overestimates their water use. The actual curtailed use would be significantly less. Attachment A shows IDWR's analysis of curtailment of 479,200 acres of junior groundwater irrigation within the current area of common groundwater supply. The volume of curtailed consumptive use would be approximately 1.09 MAF/year, an average rate of 1,509 cfs. ESPAM2.1 predicts that 16.9 cfs, which is approximately 1.1% of the curtailed use, would accrue to the Rangen spring cell.

IDWR staff comments regarding expert reports submitted on behalf of FMID

Contor (2012a, p. 5) states, "*The determination and application of a Deminimus* (sic) *effect is a policy question that will not be addressed in this report. The concept of uncertainty may be considered in making this policy determination, and uncertainty will be addressed. A Deminimus* (sic) *policy could be defined in terms of Capture Fraction, specifying a threshold fraction below which propagating effects are considered Deminimus* (sic). *This is essentially the definition of a Trim Line which has been applied in administration of water calls using ESPAM1.1. The policy could also specify a threshold total volume or volume per time, below which effects are considered Deminimus* (sic). *This is the concept that has been applied in use of ESPAM1.1 for water-right transfers. ESPAM2.0 can be operated to calculate either of these potential Deminimus* (sic) *thresholds*." IDWR staff agree that ESPAM2.1 can be used to calculate either of these types of de minimis thresholds, but do not recommend attempting to quantify model uncertainty to make a de minimis policy determination. As noted by Contor (2012a), model uncertainty is generally greater when smaller areas of the regional ESPA model are considered. Therefore, the uncertainty associated with predicting the response to curtailment within a small area defined by a trimline is likely to be greater than the uncertainty associated with predicting the response to curtailment throughout the ESPA. Further, uncertainty does not mean that it is uncertain whether or not there will be a response to curtailment, it means there is uncertainty in the magnitude of the

[5] http://www.idwr.idaho.gov/Browse/WaterInfo/ESPAM/meetings/2012_ESHMC/11_9_2012/E121025A001_spresdsheets.zip/mudflow (last visited February 20, 2013.

EXHIBIT "504"
Page No. 46 of 81

001993

response. As shown in the IDWR predictive uncertainty analysis (Wylie, 2012) and the alternative conceptual models developed by Brendecke (2012), ESPAM2.1 appears to do a good job of predicting whether or not curtailment will result in a measurable amount of water at a given spring or river reach.

On page 24, Contor (2012a) states "*The IDWR Predictive Uncertainty work indicates that the difference between two Calibrated ESPAM2.1-framework models can exceed 500% for some questions, though it is generally much smaller*." IDWR staff disagree with this statement. The IDWR Predictive Uncertainty work does not indicate predictive uncertainty exceeding 500%. Further, high percentage differences in predictive uncertainty are misleading in cases where the predicted response is small. For example, if ESPAM2.1 predicts a response of 0.02 cfs at a given location, and the alternative model calibration predicts a response of 0.04 cfs at the same location, the percentage difference would be 100%, but both models indicate that the response at that location is insignificant.

On page 24, Contor (2012a) state, "*For any particular questions, quantity uncertainty is probably at least in the range of the 17% result obtained from the water-budget analysis*." IDWR staff have not conducted a detailed review of Mr. Contor's analysis, but note that this range of uncertainty does not prevent the model from providing a useful prediction of whether or not curtailment will result in a measurable amount of water at a given spring or river reach. For example, if a range of ±20% is applied to the ESPAM2.1 predicted responses to curtailment within the model domain, a response between 14.3 and 21.5 cfs would be expected at the Rangen spring cell and a response between 194 and 291 cfs would be expected at the Buhl to Lower Salmon Falls reach. Even with this range of uncertainity, the model tells us that a model-wide curtailment would result in a measurable amount of water at the Rangen spring complex and the Buhl to Lower Salmon Falls reach. The model also tells us that only a very small fraction (approximately 1%) of the benefit of a model-wide curtailment would accrue to the Rangen spring complex. The majority of the curtailed water use would benefit other springs and reaches of the Snake River.

On pages 5-6, Contor (2012a) presents results of simulating curtailment of groundwater use junior to July 13, 1962 within the Egin Bench area of the Freemont Madison Irrigation District. Mr. Contor used ESPAM2.0 to perform this analysis and did not update the analysis with ESPAM2.1. Mr. Contor estimated that curtailment of groundwater use within the Egin Bench would reduce pumping by 4,730 acre feet per year and that after 150 years, the cumulative benefit to the Buhl to Lower Salmon Falls reach would be 1.90 acre feet (0.04% of the curtailed use), in response to a single year of curtailment. It is not clear how Mr. Contor estimated the volume of curtailed use. Mr. Contor did not simulate continuous curtailment, thus this simulation does not represent conditions that would occur if these groundwater users were curtailed for multiple years in response to an ongoing spring delivery call. IDWR staff review indicates that steady state response functions in model cells containing points of diversion for FMID groundwater irrigation rights range from 0.004% to 0.05% with respect to the Rangen spring cell, and 0.05% to 0.78% with respect to the Buhl to Lower Salmon Falls springs. The average response function, weighted by irrigation diversion rate, is 0.04% with respect to the Rangen spring cell and 0.55% with respect to the Buhl to Lower Salmon Falls springs. This indicates that Mr. Contor's methods underestimate the fractional response to a continuous curtailment at the Buhl to Lower Salmon Falls reach by an order of magnitude. Although the steady state response predicted by

EXHIBIT "504"
Page No. 47 of 81

001994

ESPAM2.1 at the Buhl to Lower Salmon Falls springs is not as small as indicated by Mr. Contor's analysis, it is still a small fraction of the curtailed use, with greater than 99% of the curtail use accruing to other reaches of the Snake River.

On pages 8 and 23, Contor (2012a) recommends that ESPAM2.1 not be used to predict responses at reaches smaller than the distances between nearby transmissivity pilot points. Figure 13 shows the ESPAM2.1 transmissivity pilot points in the vicinity of the Rangen spring cell and Buhl to Lower Salmon Falls reach. The Rangen spring cell is a one-square-mile model cell. The Buhl to Lower Salmon Falls reach is comprised of 24 model cells. The spacing between pilot points in the vicinity of the Buhl to Lower Salmon Falls reach is generally between two and four miles. If Mr. Contor's recommendation is applied, ESPAM2.1 would be used to predict the response at the Buhl to Lower Salmon Falls reach, because it is the smallest calibration reach that is greater than four miles in length.

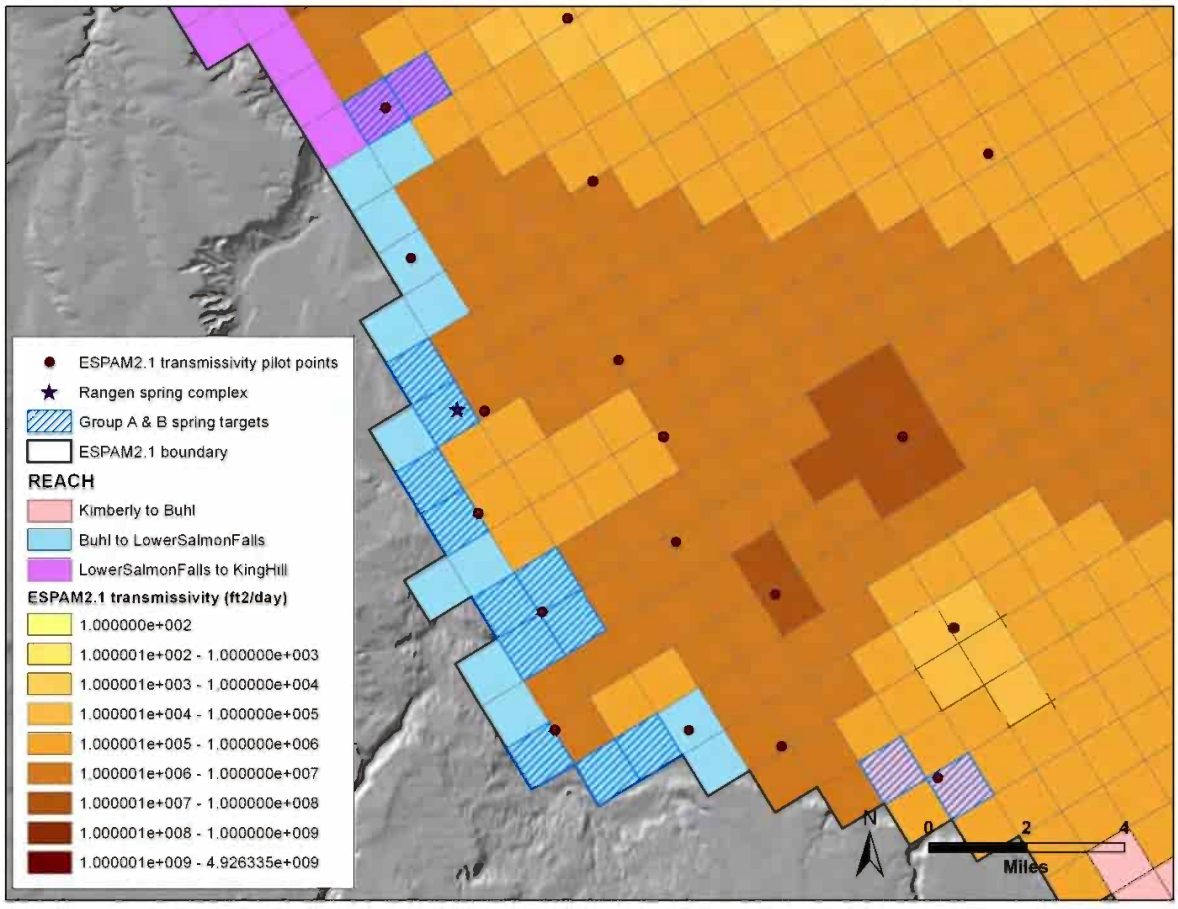

Figure 13. ESPAM2.1 transmissivity pilot points in the vicinity of the Buhl to Lower Salmon Falls reach.

EXHIBIT "504"
Page No. 48 of 81

Mr. Contor does not recommend a method for apportioning the ESPAM2.1-predicted response at the Buhl to Lower Salmon Falls reach to the Rangen spring cell, stating on page 6, "*However, no attempt has been made to apportion these benefits to individual diversions*." If Mr. Contor's recommendation is applied, a method for apportioning the reach benefit to spring cells would be needed to predict the response at the Rangen spring cell. In response to Mr. Contor's recommendation, IDWR staff performed analyses using ESPAM2.1 to predict the response at the Buhl to Lower Salmon Falls reach to curtailment of groundwater irrigation junior to July 13, 1962. IDWR analyses indicate that the response at the reach would be 242 cfs in response to curtailment within the entire model domain, 229 cfs in response to curtailment within the current area of common groundwater supply, and 198 cfs in response to curtailment within the area delineated by a 10% steady state response (Figure 14) and the area of common groundwater supply. Model results are provided in Attachment B.

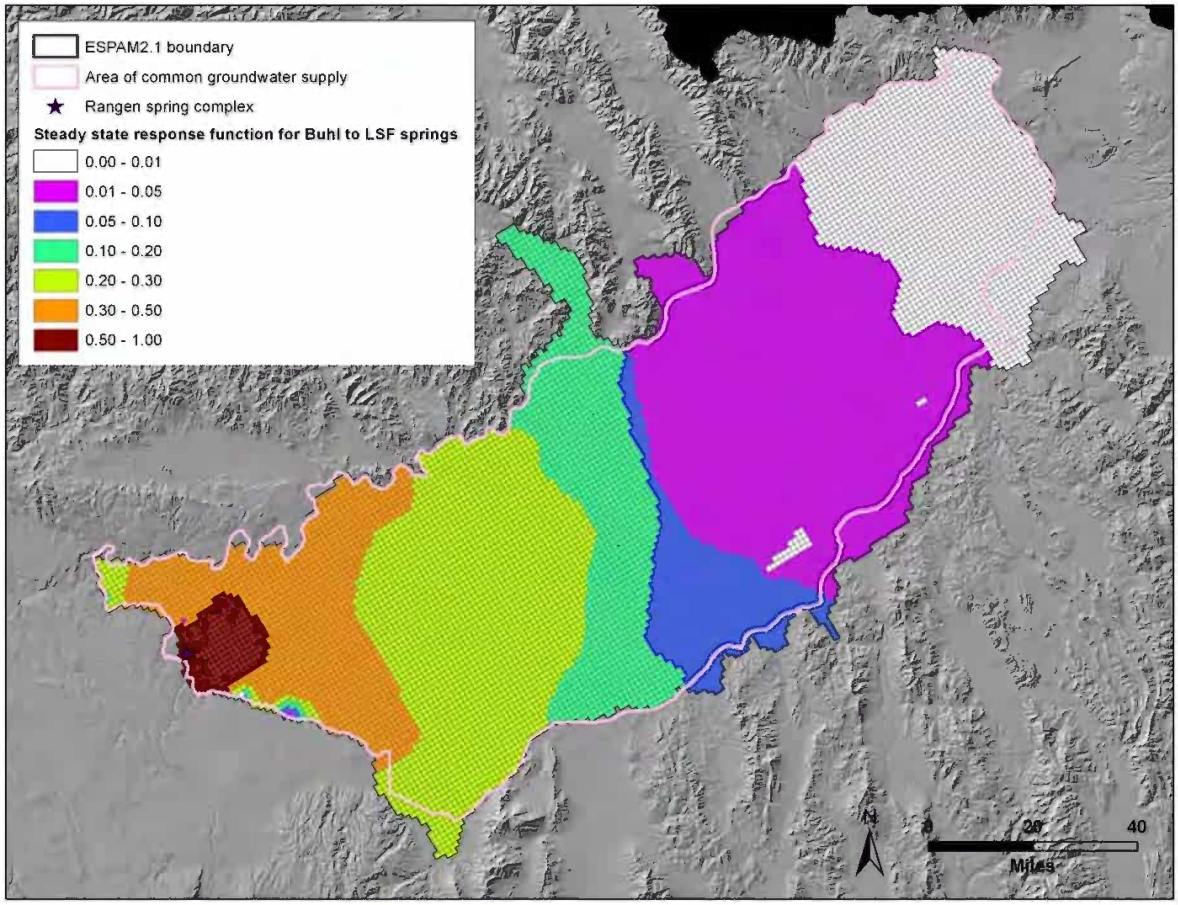

Figure 14. Steady state response functions indicating portion of curtailed use that would accrue to springs in the Buhl to Lower Salmon Falls reach.

EXHIBIT "504"
Page No. 49 of 81

IDWR staff considered two methods for apportioning the response at the reach to the Rangen spring cell. IDWR staff consider both of these methods to be inferior to using ESPAM2.1 directly to predict the response at the Rangen spring cell.

1. Use the Covington and Weaver ratio method previously used with ESPAM1.1 to apportion discharge to the Rangen spring complex. This method is identical to the method used with ESPAM1.1 except that the Covington and Weaver discharge values for Thousand Spring and the Three/Weatherby spring complex were updated[6]. Based on the Covington and Weaver discharge estimates of 35.5 cfs for the Rangen spring complex and 2,852 cfs for all spring in the reach, a ratio of 0.0124 was multiplied by the ESPAM2.1-predicted response at springs within the reach. This method results in a predicted accrual of 2.9 cfs at the Rangen spring complex in response to model-wide curtailment and 2.4 cfs in response to curtailment within a 10% trimline for the reach. This method is inferior to using the ESPAM2.1 prediction for the Rangen spring cell, because it considers fewer data than ESPAM2.1, neglects regional hydrogeologic conditions that are modeled in ESPAM2.1 at a scale smaller than the 24 cell reach, neglects the spatial distribution of aquifer recharge and discharge, and neglects the sensitivity of higher elevation springs to changes in aquifer head. Figure 15 illustrates how this method provides a poorer prediction of discharge at the Rangen spring complex than ESPAM2.1. Use of this method with ESPAM1.1 was necessary because the discharge data compiled for calibration of ESPAM2.1 were not available for use with ESPAM1.1. The additional data currently available allow development of better methods for predicting the response at the Rangen spring cell.

[6] See attribute field ESPAM2_cfs in http://www.idwr.idaho.gov/Browse/WaterInfo/ESPAM/monitoring_data/Springs/Covington_Weaver_Spgs.zip/Covington_Weaver_Spgs.shp (last visited February 20, 2013).

EXHIBIT "504"
Page No. 50 of 81

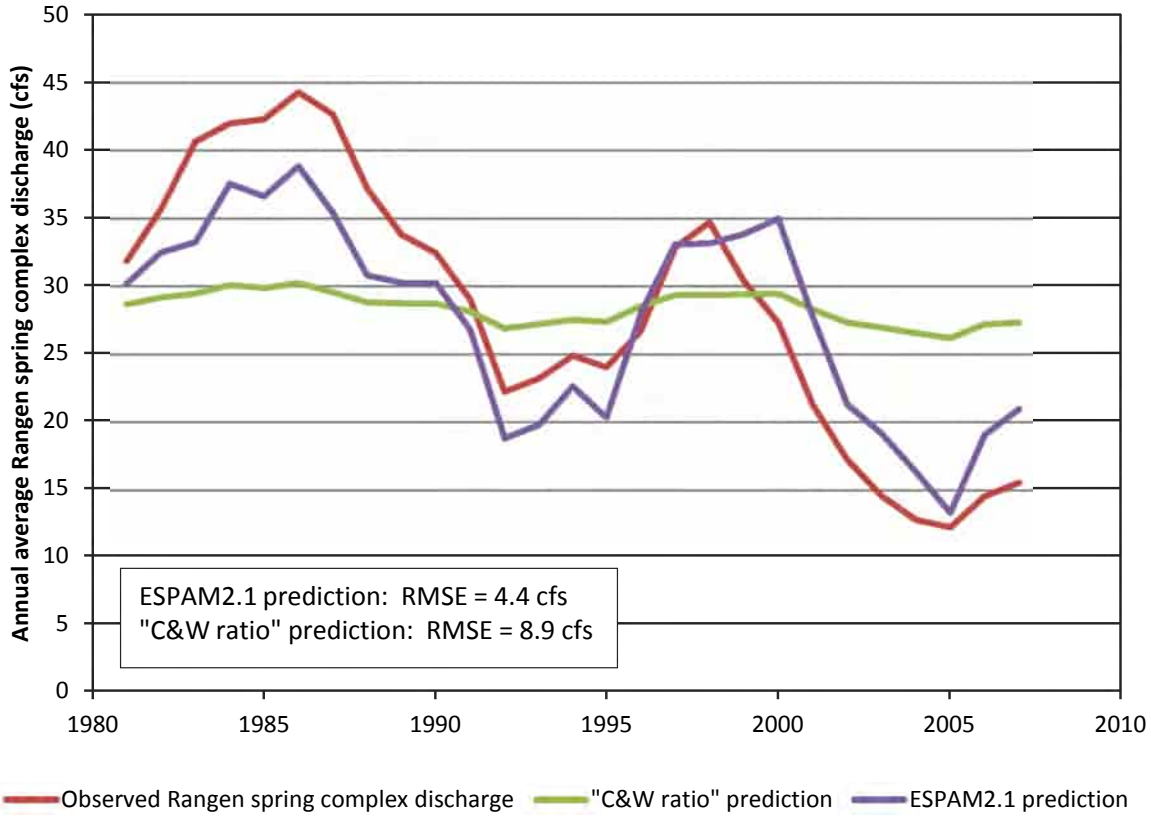

Figure 15. Comparison of Covington and Weaver ratio prediction method and ESPAM2.1 prediction of discharge at Rangen spring cell.

2. Use a linear regression of Rangen spring complex discharge with reach gain to predict change in Rangen spring discharge corresponding to the modeled change in reach gain (Figure 16). This method predicts a 0.028 cfs change in Rangen spring complex discharge per unit cfs change in reach gain, resulting in a predicted accrual of 6.8 cfs at the Rangen spring complex in response to model-wide curtailment and 5.5 cfs in response to curtailment within a 10% trimline for the reach. This method is inferior to using the ESPAM2.1 prediction for the Rangen spring cell, because it considers fewer data than ESPAM2.1, neglects regional hydrogeologic conditions that are modeled in ESPAM2.1 at a scale smaller than the 24 cell reach, and neglects the spatial distribution of aquifer recharge and discharge. This method is a slight improvement over the Covington and Weaver ratio method, because it incorporates some consideration of the sensitivity of higher elevation springs to changes in aquifer head. Figure 17 illustrates how this method provides a poorer prediction of discharge at the Rangen spring complex than ESPAM2.1, but a better prediction than the Covington and Weaver ratio method.

IDWR staff comments regarding expert reports submitted on behalf of the City of Pocatello

IDWR staff review indicates that ESPAM2.1 steady state response functions for model cells containing groundwater points of diversion for the City of Pocatello range from 0.37% to 0.47% with respect to the Rangen spring cell. Based on the response functions, IDWR staff agrees with Sullivan (2012) that curtailment of the City of Pocatello's groundwater use will result in a negligible increase in discharge at the Rangen spring complex. ESPAM2.1 predicts that more than 99.5% of the curtailed use would benefit other springs and reaches of the Snake River.

Sullivan (2012) provided a copy of the results of an IDWR analysis of the response at the Rangen spring cell to curtailment within various areas defined by steady state response functions. These analyses limited the area of curtailment to areas where the fraction of curtailed use accruing to the Rangen spring cell exceed values ranging from 0.2% to 10%. The results of the analyses performed by IDWR and submitted by Mr. Sullivan were calculated with ESPAM2.0 and were not updated using ESPAM2.1. IDWR staff updated these analyses with ESPAM2.1 in response to Mr. Sullivan's submittal. The results are provided in Table 4 and Figure 18. These results supersede the results presented by Mr. Sullivan in his Figure 8-4.

Area of curtailment[7]	Curtailed groundwater irrigation (ac)	ESPAM2.1 predicted response at Rangen spring cell (cfs)	Acres curtailed per cfs of benefit at Rangen spring cell (ac/cfs)
Model Boundary	565,026	17.89	31,591
Area Common Ground Water Supply (CGW)	479,203	16.94	28,296
CGW 0.2% trim line	257,673	16.15	15,956
CGW 1% trim line	160,389	14.55	11,022
CGW 1.5% trim line	154,270	14.32	10,774
CGW 1.7% trim line	108,543	11.84	9,167
CGW 2% trim line	67,093	9.31	7,210
CGW 3.5% trim line	26,694	5.71	4,678
CGW 5% trim line	12,346	3.35	3,689
CGW 10% trim line	24	0.01	1,868

Table 4. IDWR analysis of response to curtailment within various areas.

[7] Trim lines used to define the area of curtailment were delineated to include model cells where greater than a given percentage of the curtailed use will accrue to the Rangen spring cell. This method relies on ESPAM2.1 predictions of response at the Rangen spring cell. The area within the trim line was also clipped to exclude areas outside of the current area of common groundwater supply.

9. Woodling, J.D., 2013. *Expert Rebuttal Report in the Matter of Distribution of Water to Water Right Nos. 36-02551 and 36-07694*, prepared on behalf of the City of Pocatello.

Summary of rebuttals on behalf of Rangen

Brockway et al. (2013a) respond to the expert reports submitted on behalf of IGWA by Brendecke (2012), Hinckley (2012), Rogers (2012) and the expert report submitted on behalf of the City of Pocatello by Sullivan (2012). Brockway et al. (2013a) "*assert that the water rights issued by IDWR for the Rangen facility and the administration of those define and treat the entire Range Spring as a single source*." Brockway et al. (2013a) reiterate their opinions that ESPAM2.1 is the best available scientific tool for evaluation of responses to changes is ESPA water use and that uncertainty analyses performed on ESPAM2.1 and other ESPA groundwater models do not support the use of the trimline proposed by Brendecke (2012).

Brockway et al. (2013a, p. 2) criticize the alternative conceptual models presented by Brendecke (2012), stating, "*Hypothetical interpretations of the Rangen Spring geology offered by IGWA consultants Hinckley and Brendecke are not justified and different conceptual models, as proposed by IGWA consultants, are incorrect*," and "*These expert reports can be characterized as a sudden reversal of a decade of open and collaborative ESPAM model development led by IDWR and with the cooperation and oversight of the members of the ESHMC, including Brendecke and Sullivan*." Brockway et al. (2013a, p. 17) also note that Dr. Brendecke's alternative models predict similar responses to curtailment at the Rangen spring complex and state, "*The similarities between the results from alternative models presented by Brendecke and results from ESPAM2.1 prove that ESPAM2.1 is a robust model. Even when inappropriate changes are made to the conceptualization of the model, it predicts virtually the same Rangen Spring response to full ESPA curtailment of junior ground water pumping*."

Brockway et al. (2013a) provide additional discussion of Rangen's water measurement methods and reiterates their opinion that historic flow measurements at the Rangen facility are accurate and adequate for the purposes for which they have been used, including calibration of ESPAM2.1. Brockway et al. (2013a) criticizes the Sullivan (2012, p. 6) analysis of Rangen's beneficial use and efficiency of water use, stating, "*This assumption reflects an un-familiarity with the operation of aquaculture facilities which require periodic harvesting and movement of stock within the facility which results in temporary non-use of specific raceways or rearing facilities*.

EXHIBIT "504"
Page No. 55 of 81

002002

Brockway et al. (2013b) respond to the expert reports submitted on behalf of FMID by Contor (2012a, 2012b). Brockway et al. (2013b) criticize the Contor (2012a) analysis of model uncertainty, and disagree with Mr. Contor's conclusion that transmissivity uncertainty is approximately equal to water budget uncertainty. They also question how Mr. Contor calculated the 17% estimate of water budget uncertainty, and criticize statements made by Mr. Contor regarding the results of IDWR's uncertainty analysis.

Smith (2013) responds to expert reports submitted on behalf of IGWA by Church (2012) and Rogers (2012) and on behalf of the City of Pocatello by Sullivan (2012). Mr. Smith states that pumped water and reused water are less desirable than first use spring water because of dissolved oxygen concentrations, concentration of waste, and potential failure due to loss of power. Mr. Smith asserts that the hatcheries using pumped water and recycled water mentioned by Rogers (2012) are federal or state hatcheries that do not have to make a profit to operate. Mr. Smith asserts that pumped water is too unreliable for large commercial hatcheries and that recirculation hatcheries are subject to catastrophic losses of fish to pumping failures, nitrite toxicity and disease outbreaks such as infectious hematopoietic necrosis (IHN). Mr. Smith submitted a copy of an expert report submitted by John R. MacMillan on behalf of Clear Springs Foods in a previous proceeding and stated that he is in general agreement with Dr. MacMillan's report. Smith (2013) also discusses errors in calculations presented by Rogers (2012).

Smith (2013) reiterates his conclusions that the flow indices and density indices used by Rangen for the purpose of raising fish for Idaho Power Co. are reasonable, the Rangen hatchery is currently beneficially using all available water and not wasting water, and that the hatchery could use more water to raise fish if it was available.

Green (2013) responds to Church (2012) and states, "*My opinion of Mr. Church's analysis is that his analysis is incomplete and inaccurate*." Mr. Green states that Idaho farm raised trout is a multi-million dollar business and that Idaho trout production capacity is a substantial portion of the U.S. total trout production, and that the U.S. trout producing industry is not in decline. Mr. Green criticizes Mr. Church's assertion that Rangen should use their own money to make efforts to remedy a problem caused by junior groundwater pumping. Mr. Green concludes, "*Ronald Coase, a Nobel Prize winning economist, suggests the persons' imposing an externality, ground water farmers, on other property owners, Rangen, can and should compensate the damaged party, Rangen*."

Summary of rebuttals on behalf of IGWA

Hinckley (2013) responds to Brockway et al. (2012). Mr. Hinckley reiterates his opinion that ESPAM2.1 does not adequately represent aquifer geometry and hydrogeologic conditions in the area of the Rangen spring complex. Mr. Hinckley also reiterates his opinion that Rangen should obtain additional water by constructing a vertical well in the ESPA, or by developing another horizontal tunnel below Curren Tunnel.

EXHIBIT "504"
Page No. 56 of 81

002003

Brendecke (2013) responds to Brockway et al. (2012) and reiterates his opinions that ESPAM2.1 is a regional model that cannot be relied upon to accurately predict effects at Rangen from curtailment of junior groundwater rights, that Rangen consistently underestimates available flows, that Rangen could pump additional water to its small raceways, and that Rangen should make improvements to Curren Tunnel or construct a vertical well. Dr. Brendecke states that the Brockway et al. (2012) simulation of curtailment throughout the model domain ignores the statutory definition of the area of common groundwater supply, and that "*delivery of less than 1% of the curtailed use to the calling water right constitutes a waste of water by any reasonable definition*."

Rogers (2013) responds to Smith (2012), Brockway et al. (2012), and Sullivan (2012) and reiterates his opinions that Rangen does not maximize fish production, is not using water efficiently, and is wasting water currently available to the hatchery. Mr. Rogers also reiterates his opinion that Rangen should consider pumping systems, reuse of water, and developing new wells to enhance flows.

Summary of rebuttals on behalf of the City of Pocatello

Sullivan (2013) responds to Brockway et al. (2012) and Smith (2012). Mr. Sullivan provides a detailed discussion regarding the accuracy of Rangen flow measurement procedures and concludes that "*significant under-measurement of the flows during the calibration period calls into question the model calibration to the Curren spring flows, and would likely require that the model be re-calibrated*." Mr. Sullivan points out that he and Chuck Brendecke qualified the ESHMC recommendation for ESPAM2.1 with "*although other tools or models may be more appropriate in certain circumstances*." Mr. Sullivan argues that Rangen has not shown material injury and states, "*No data or analyses were provided to support the opinion that Rangen would increase fish production with additional flow*," and, "*An overarching implication in the Brockway Report is that depletions predicted by the ESPAM2.1 model from junior ground water users equals injury. This is not how the prior versions of the ESPAM have been used in delivery calls. Only after it has been proven that a senior water user is suffering material impacts due to water shortages…has the Department used the ESPAM to assess the magnitude of the shortage…*"

IDWR staff comments regarding rebuttals on behalf of Rangen

On page 4, Brockway et al. (2013a) state "*The best estimate of the impact of junior groundwater pumping on Rangen spring is the unmodified output from ESPAM2.1. Utilization of a trimline of any percentage magnitude, justified by an unsubstantiated estimate of ground water model uncertainty, arbitrarily limits the true hydraulic impact of junior pumping and is not hydraulically or statistically supported. There has never been an uncertainty analysis performed on ESPAM2.1 or any ESPA ground water model to support the use of a trimline as currently configured*." IDWR staff agree that ESPAM2.1 provides the best prediction of the impact of junior groundwater pumping on spring discharge in the Rangen spring cell. This conclusion applies both to the ESPAM2.1-predicted response to model-wide curtailment and to the ESPAM2.1-predicted steady state response functions. These response functions provide the best prediction of the percentage of curtailed groundwater use that would accrue to the Rangen spring cell, and the percentage of curtailed use that would accrue to other springs and reaches

EXHIBIT "504"
Page No. 57 of 81

002004

of the Snake River. This information can be used to delineate a trimline, if the Director finds it is not appropriate to curtail groundwater users if less than a certain percentage of their curtailed use would accrue to the Rangen spring cell.

On page 14, Brockway et al. (2013a) provide results of curtailment simulations performed using the alternative models presented by Brendecke (2012). Their results are identical to those obtained by IDWR and presented previously in the section "IDWR staff comments regarding submittals on behalf of IGWA".

On page 15, Brockway et al. (2013a) provide a table of response functions for seven model cells in the Rangen area. Their results are identical to those obtained by IDWR and discussed previously in the section "IDWR staff comments regarding submittals on behalf of IGWA".

IDWR staff comments regarding rebuttals on behalf of IGWA

On page 1, Hinckley (2013) asserts that ESPAM2.1 represents the aquifer "*as a single, 4,000-ft. thick layer*". IDWR staff disagree with this comment. ESPAM2.1 represents the aquifer using time-constant transmissivity. Transmissivity, which is the product of hydraulic conductivity and saturated thickness, is adjusted during model calibration to obtain the best fit to observed data. Neither hydraulic conductivity nor saturated thickness is explicitly represented in the ESPAM2.1, and their individual contributions to transmissivity are not relevant in a time-constant transmissivity model.

On page 1, Hinckley (2013) asserts that "*characterization of aquifer geometry is important*" and that ESPAM2.1 "*models the aquifer as being laterally continuous in all directions from the Rangen discharge points*." IDWR staff disagree with Mr. Hinckley's assertions that ESPAM2.1 ignores aquifer geometry and represents the aquifer as laterally continuous in all directions. ESPAM2.1 models the aquifer geometry and the geometry of spring discharge locations along the Snake River and Hagerman rims within the constraints of a one-square-mile model grid. While the ESPAM2.1 representation does not allow delineation of details smaller than one mile, it does provide a better representation of aquifer geometry than other available models or predictive methods.

Hinckley (2013) discusses water levels in Well No. 797 on pages 5-6 and in Figure 2. He inappropriately compares the slope of a linear regression of data collected only in the 2000s with the linear slope of water levels modeled by ESPAM2.1. It is not appropriate to use data collected only in the 2000s to evaluate ESPAM2.1, which was calibrated to data collected between 1985 and 2008. The data collected in the 2000s represents a period of relatively low net ESPA recharge, and do not reflect the range of conditions that occurred between 1985 and 2008 or the volume of net ESPA recharge that would occur if groundwater pumping junior to 1962 was curtailed. As shown previously in Figure 12, curtailment of groundwater pumping junior to 1962 would result in net ESPA recharge similar to the late 1990s. Further, IDWR staff disagree with the use of Well No. 797 by both Brockway et al. (2012) and Hinckley (2013) for prediction of impacts at the Rangen spring complex. This well is located approximately 6.5 miles north of the Rangen spring complex and has a significantly different spatial relationship to junior irrigated lands in this area. Well No. 989 would be a more appropriate well to use for prediction of

EXHIBIT "504"
Page No. 58 of 81

002005

impacts at the Rangen spring complex, as discussed previously in the section "IDWR staff comments regarding submittals on behalf of IGWA."

Hinckley (2013) discusses water levels in Well No. 991 on page 6 and in Figures 3a and 3b. This well was not used to calibrate ESPAM2.1, because water levels and the well driller's report indicate that it is not completed in the ESPA. The maximum water level elevation in this well is approximately 3,007 feet, more than 80 feet lower than the elevation of Spring Creek Spring, which is the lowest elevation spring in the same model cell. This well is not included in the shapefile, Wells.shp[8], which shows the wells used as calibration targets. Water level measurements for this well are included in the spreadsheet ESPAM2_ESPAM21.xlsm[9], but all measurements are weighted zero, indicating that they were not used to calibrate the model.

On page 2-2, Brendecke (2013) compares historic measurements of 50 cfs in April 1902 and 96 cfs in September 1917 and suggests the difference between these measurements may be seasonal variation in discharge from the Rangen spring complex. As previously discussed in response to Brockway et al. (2012), IDWR staff review of these historic records indicates that these measurements were likely collected at two different locations along Billingsley Creek, and it is likely both measurements include more than just the discharge from the Rangen spring complex.

On page 4-1, Brendecke (2013) states, "*There is nothing in the Department's report on this comparison that attributes the increase in curtailed consumptive use to 'increased confidence in model inputs and calibration targets'. Most changes in model inputs were associated with extension of the model period and disaggregation to monthly stress periods. The curtailment difference is largely due to the use of different time periods to represent current conditions.*" This statement does not reflect the conclusions presented by IDWR in Sukow (2012a), which stated that most of the increase in junior irrigated land area resulted from improvements in GIS methods used to delineate irrigation lands. Sukow (2012a) also stated that changes in estimates of crop irrigation requirements result largely from changing from 1971-2000 average precipitation used with ESPAM1.1 to a November 1998 to October 2008 average precipitation with ESPAM2.1. The 1971-2000 period used to estimate precipitation with ESPAM1.1 curtailment simulations resulted in estimates of precipitation higher than the long term average from 1934 through 2008. Average precipitation from the 1998-2008 period used with ESPAM2.1 curtailment simulations is closer to the long term average.

On page 4-2 and Table 4.1, Brendecke (2013) states that differences between ESPAM2.0 and ESPAM2.1 predictions of responses to curtailment differed by up to 30%. IDWR staff note that the prediction which changed by up to 30% was the prediction of the response at the Ellison spring cell, which is a Group C spring and had an insignificant response (0.115 cfs in ESPAM2.0 and 0.162 cfs in ESPAM2.1).

EXHIBIT "504"
Page No. 59 of 81

Model calibration with respect to Group C springs is not well constrained, because the Group C springs do not have transient calibration targets. The difference between the ESPAM2.0 and ESPAM2.1 predictions of response at the Rangen spring cell was only approximately 1%, suggesting that the Group B transient target for the Rangen spring cell adequately constrains model calibration with respect to the Rangen spring cell.

On page 4-3, Brendecke (2013) states, "*seasonal water level fluctuations and predicted water level changes (due to curtailment) are nearly 100% of the saturated thickness above the Tunnel and about 10% of the thickness above the lower springs at Rangen."* He states that the use of time-constant transmissivity in ESPAM2.1 was not justified. As stated in the ESPAM2.1 final report (IDWR, 2013), "*The generally considerable saturated thickness of the ESPA supports a time-constant representation of transmissivity, because drawdown is generally expected to be less than 10% of total saturated thickness (Anderson and Woessner, 1992)*." Note that this guideline applies to water level change as a percentage of the total saturated thickness, which Dr. Brendecke acknowledges is about 10%. The portion of the saturated thickness that is above the tunnel elevation is not relevant, because the tunnel is not located at the base of the aquifer. The conditions described by Dr. Brendecke are at the limit of the standard cited in IDWR (2013), but do not exceed this standard.

On page 4-3, Dr. Brendecke asserts, "*The curtailment scenario discussed by Rangen represents a 'new distribution of stress' as described by Reilly (1987)*." As shown previously in Figure 12, curtailment of groundwater use junior to 1962 would result in net ESPA recharge within the range that occurred during the model calibration period. Because the model is calibrated using net recharge, not the groundwater pumping portion of net recharge, the comparison made by Dr. Brendecke in Figure 4-1 is not relevant.

On page 4-6, Dr. Brendecke states, "*The consistent over-prediction of low flow values in recent years is problematic because this is the starting point for any changes due to curtailment*." Dr. Brendecke again overstates the importance of conditions during recent drought conditions. The best modeled representation of a system is obtained with calibration to a range of conditions. This was accomplished with ESPAM2.1 by calibration during a 23.5-year period that included both wet and dry years. Low flow values in recent years are not more important than flow values in the 1980s or 1990s. For predicting the response to curtailment, it is the difference between low flow values and historic values that is most important. Over-prediction of low flow values in recent years and under-prediction of flows in the 1980s likely results in slightly lower predictions of the response to curtailment. This is illustrated by Dr. Brendecke's alternative model (AMEC Model 2), which Brendecke (2012) states "*appears to resolve the overprediction problem noted for ESPAM2.1 in recent years*." AMEC Model 2 predicts a response of 18.0 cfs in response to curtailment within the model domain, which is slightly higher than the ESPAM2.1-predicted response of 17.9 cfs.

On page 4-7, Brendecke (2013) states, "*…the inability to quantify uncertainty does not disprove its existence or demonstrate that it should be ignored*." IDWR staff agree that model uncertainty exists and do not suggest that it should be ignored. However, there is no evidence to support Dr. Brendecke's assumption that model uncertainty is so high that ESPAM2.1 cannot reliably predict whether or not the response to curtailment at the Rangen spring complex would be a measurable amount of water.

EXHIBIT "504"
Page No. 60 of 81

002007

Accepting the predictions made by ESPAM2.1 as the best available prediction is not ignoring model uncertainty. Actual responses may be higher or lower than the prediction, so adjusting a model prediction in one direction would favor one party over another. IDWR staff also note that delineation of a trimline using ESPAM2.1-predicted response functions is not a "*modification of the output*" as stated in the Brockway et al. (2012) quote that Brendecke (2013) is responding to on page 4-7. Delineation of a trimline using ESPAM2.1-predicted response functions is a direct application of unmodified ESPAM2.1 predictions of response at the Rangen spring complex. The steady state response functions are subject to the same types of uncertainty as the predicted response to model-wide curtailment. Use of the steady state response functions to delineate a trimline requires accepting that the ESPAM2.1 provides the best available prediction of response at the Rangen spring cell.

On page 4-7, Brendecke (2013) states regarding the 2009-2010 validation scenario, "*This is important since curtailment would begin with present, rather than historical, aquifer conditions*." IDWR staff disagree with this statement. Curtailment of groundwater use would increase the net ESPA recharge to historic conditions reflected during the calibration period in the 1990s (Figure 12). Present conditions are not more relevant than historic conditions.

On page 7-1, Brendecke (2013) states, "*Relatively modest changes to the model demonstrate quite different model results*." IDWR staff review of Dr. Brendecke's modified alternative models indicates that his models actually demonstrate quite similar results, as presented previously in the section "IDWR staff comments regarding expert reports on behalf of IGWA".

On page 7-3, Brendecke (2013) states, "*Good model calibration is a necessary but not sufficient condition for reliable model prediction. Reliable prediction also requires accurate model representation of hydrologic and hydrogeologic conditions in the area of the prediction. ESPAM2.1 does not contain this detailed representation*." In the opinion of IDWR staff, ESPAM2.1 is capable of providing a reasonable prediction of the response at the Rangen spring cell to regional stresses in the ESPA, such as curtailment of groundwater use. ESPAM2.1 does represent the aquifer geometry and regional hydrogeologic conditions within the constraints of a one-square-mile model grid and the transmissivity pilot point spacing, which is generally two to four miles in the vicinity of the Buhl to Lower Salmon Falls reach. ESPAM2.1 considers more hydrologic and hydrogeologic data than any other method available for predicting the response at the Rangen spring cell.

IDWR staff comments regarding rebuttals on behalf of the City of Pocatello

On pages 5-14, Sullivan (2013) discusses the accuracy of Rangen's flow measurements and rebuts statements made by Brockway et al. (2012). IDWR staff have reviewed Rangen's flow measurement methods during previous proceedings and have a number of comments in response to Sullivan (2013) and Brockway et al. (2012, 2013).

Rangen submitted annual water measurement reports directly to IDWR from 1995 through 2009, and to Water District 36A from 2010 to 2012. IDWR has accepted these annual water measurement reports

EXHIBIT "504"
Page No. 61 of 81

002008

during this period of record understanding that Rangen estimates hatchery diversions or flows using fish raceway check boards as non-standard weir measuring devices.

Based on the IDWR memorandum dated December 4, 2003 from Jennifer Berkey to Tim Luke (Berkey, 2003), reported measurement data submitted to IDWR by Rangen from 1995 through 2002 for the hatchery diversion (IDWR diversion number 410089) are the sum of the CTR raceway measurements and the measurement at the dam on Billingsley Creek (also known as the "Lodge dam"). IDWR understands that the Rangen measurement reports submitted to IDWR after 2002 are also based on the sum of the CTR raceways and the Lodge dam. The CTR raceway measurements include all water flowing through the hatchery, including the water diverted from Billingsley Creek and water diverted from the Curren Tunnel to the hatchery lab and upper raceways. Water diverted from the Curren Tunnel to the lab and upper raceways is re-diverted to the lower raceways (Large and CTR raceways). Water measured over the Lodge dam in the creek is water that bypasses the hatchery. The hatchery diversions and layout are described in the IDWR memo from Cindy Yenter to Director Karl Dreher, dated December 15, 2003 (Yenter, 2003).

Measurement of flow through the hatchery using 2-inch rectangular stop logs or check dam boards[10] (check boards) is not considered a standard methodology of measurement because the check board weirs are not considered standard measurement devices. IDWR's *Minimum Acceptable Standards for Open Channel and Closed Conduit Measuring Devices* specify that construction, installation and operation of open channel measuring devices, including contracted rectangular weirs and suppressed rectangular weirs, should follow published guidelines such as those published by the United States Bureau of Reclamation (USBR, 1997).

Although the raceway check boards are not considered standard measuring devices, IDWR accepts measurements using these structures at many hatcheries in the area given that IDWR's standards allow an accuracy of +/-10 percent for open channel measuring devices when compared to measurements using standard portable measuring devices. Many of the area hatcheries have long used raceway check board structures for measuring devices out of convenience and lack of any other installed standard type devices. Some hatchery operators have not installed standard measuring devices due to lack of suitable measurement locations and added costs associated with installing standard devices. IDWR has not calibrated or compared the Rangen raceway check board measurements against standard portable measuring device measurements due to the lack of suitable locations within the hatchery where flows can be measured with portable measuring equipment. However, IDWR staff has compared portable discharge measurements against check board structures at other hatchery and irrigation diversions in both the Hagerman area and other locations in Idaho. IDWR has found those check board measurements, when used with the standard suppressed rectangular weir equation[11] and acceptable

[10] IDWR has observed that the check boards used at the Rangen Hatchery and other area hatcheries are standard 2" x 4" boards in which the actual thickness measures 1-1/2 inches, or 0.125 ft.

[11] The Francis equation for a standard suppressed rectangular weir is $Q = 3.33 L H^{1.5}$ where Q = discharge, L = weir crest length, and H = head of water above the weir crest, and the value 3.33 is a constant coefficient (US BOR, 1997, p 7-19)

EXHIBIT "504"
Page No. 62 of 81

002009

head measurements are typically within +/- 10 percent of standard portable flow meter measurements. In her memo dated December 15, 2003, Cindy Yenter, Water District 130 watermaster, states the following:

> *"My experience has been that measurements taken at flat-crested dam boards are generally less accurate than those taken at sharp crested weirs, and that flat crested dam measurements return indications of flow which are typically 5-10% lower than actual flow, when checked against other methods of measurement."*

The Yenter memo further states that the sum of the IDWR staff measurements of the CTR raceways and Lodge dam on November 25, 2003 was 10 percent higher than the measurements taken by the Rangen staff a day earlier[12]. The memo was the basis for of Finding of Fact No. 76 in the May 19, 2005 Second Amended Order issued by Director Dreher which states in part that "*…measurement of flows through hatchery raceways reported by Rangen may be systematically about 10 percent lower than actual flows*." The Yenter memo suggests that the difference may be due largely to methods in measuring the head above the weir crest between IDWR and hatchery staff. Yenter notes that the proper location for measurement of head is upstream from the weir crest. Sullivan (2013, p. 11-12) correctly states that the head measurement for a standard weir should be upstream of the weir crest a distance of at least four times the maximum head on the crest. Yenter (2003) states that if it is not possible to obtain a proper upstream head measurement, "*the proper technique for using a hand held staff gage directly on the crest is to turn the surface of the gauge into the flow slightly, to overcome the drawdown (over the crest) and simulate a true head reading*." This method of measuring head on a weir is described in more detail in Brockway (2013) on pages 4-5. The description provided by Brockway is consistent with the methodology used by IDWR staff. IDWR rarely finds that staff gages are installed in the proper location for either standard or non-standard weirs. The method described by Yenter and Brockway therefore is used extensively by IDWR staff when measuring head at weirs found in the field where no staff gage is installed or gages are not installed in the proper location.

The other source of discrepancy between the IDWR and Rangen staff measurements noted in Yenter (2003) is the use of different weir equations or rating tables. IDWR used the standard suppressed weir equation (Francis equation), $Q = 3.33\ L\ H^{1.5}$, where Rangen used a rating table based on a modified weir equation. The table used by Rangen is found in Appendix A of the Brockway report dated December 20, 2012. This same table was also found in IDWR's records (attached) and appears to have been faxed to the IDWR Southern Region office on December 18, 2003 by Rangen staff. The table includes a rating for the Large raceways, the CTR raceways and the Lodge dam. The Large and CTR raceway ratings employ a fixed length weir crest even though the crest lengths at individual raceways vary slightly in size.

[12] IDWR staff measured a total of 18.97 cfs at the Rangen hatchery based on sum of the Large raceways + Lodge Dam, or a total of 18.69 cfs based on sum of CTR raceways and Lodge dam. The 2003 measurement report submitted to IDWR by Rangen reports a total of 17.51 cfs on November 24, 2003, which is a difference of either 1.46 or 1.18 cfs, or a difference of -7.7% and -6.31% respectively. IDWR measured 0.48 cfs at the Lodge dam on November 25, 2003.

EXHIBIT "504"
Page No. 63 of 81

When using the IDWR head measurements from November 25, 2003 with the Rangen discharge table, the flow at the Large raceways is 16.9 cfs and the flow at the CTR raceways is 16.2 cfs. The Yenter memo states that Rangen staff measured 16.6 cfs and 15.9 cfs at the Large and CTR raceways respectively on November 24, 2003, a difference of only 0.3 cfs between IDWR and Rangen when using the Rangen discharge table, or a difference of less than 2 percent at each set of raceways. The relatively minor differences between the IDWR and Rangen measurements when using the Rangen discharge tables indicates that the differences in flow measurements between IDWR and Rangen on November 25th and 24th, 2003, was due mostly to the use of different weir equations or rating tables, rather than differences in head measurements.

Page 9 of Brockway (2012) indicates that the Rangen rating table "appears to match most closely with a standard rectangular contracted weir formula with a coefficient of 3.09 rather than the typical 3.33 coefficient." IDWR staff note that use of this formula with the 3.09 coefficient yields values that are slightly different than the values in the Rangen table. Columns 5 and 6 of Tables 1-3 through 1-5 in the SWE rebuttal report show the coefficients derived from both the suppressed weir and contracted weir equations using the Rangen rating table. As seen in Tables 1-3 through 1-5 the coefficients used in the Rangen rating table range from 2.85 to 3.20.

Brockway (2012) states that the Rangen rating tables "*are likely to be more accurate*" than a standard rectangular weir discharge using USBR weir flow calculations, but the report does not provide an explanation for the improved accuracy. Brockway (2013) on page 5 states the following:

> *"Studies conducted on flow over check boards at the ends of raceways on aquaculture facilities indicate that the weir coefficient that should be used for flow over check boards, is near 3.09 as compared to the standard Francis formula, which assumes a sharp crested weir with a coefficient of 3.33 (USBR Water Measurement Manual, 1967). King and Brater, (Appendix A), 1967 compiled research on broad crested weir coefficients which shows a weir coefficient for use on a broad crested weir of approximately 2-inch width of 3.08. This would be applicable to flow over check boards with heads between 3 and 4.5 inches (0.25 to 0.38 ft.)"*

Sullivan (2013, p. 7) cites King and Brater, 1976, whereby the standard suppressed rectangular weir equation with a coefficient of 3.09 is used as the standard broad crested weir equation.

The statements from Dr. Brockway above with respect to use of a standard contracted weir equation with a 3.08 coefficient that is more appropriate for a broad crested weir raise the following concerns:

1) IDWR's review of the 1984, 1997 and 2001 editions of the USBR Water Measurement Manual confirm that a coefficient of 3.33 is used for standard sharp crested thin plate weirs. However, IDWR's review of the USBR manuals found no mention or reference to studies conducted on flow over check boards in aquaculture raceways and the recommended use of a coefficient of either 3.09 or 3.08 when using 2-inch thick check boards.

EXHIBIT "504"
Page No. 64 of 81

002011

2) As shown in Table 1-1 of Sullivan (2013), which is taken from King and Brater, 1976, a broad crested weir coefficient of 3.08 corresponds to a crest breadth (or width) of 0.5 ft. and head of 0.6 ft., as well as a crest breadth of 1.0 ft. and head of 1.2 ft. The 2-inch thick check boards used at the Rangen facility represents a crest width of about 0.17 ft. As stated on page 7-2 of the USBR Water Measurement Manual, 1997, "true broad crested weir flow occurs when upstream head above the crest is between the limits of 1/20 and 1/2 the crest length in the direction of flow" (between 0.05 and .50). Additionally, Bos (1989) states that for use of broad crested weirs, the length of the weir crest in the direction of flow (L) should be related to the total energy head (H) over the weir crest as: $0.07 \leq H/L \leq 0.50$. A crest width of 2 inches (0.17 ft) and a head of 4.5 inches (0.38 ft.) referenced by Dr. Brockway results in the ratio H/L being equal to 2.24, thereby exceeding the recommended ratio provided in both Bos (1989) and the USBR (1997). Moreover, a description of a broad crested weir provided in Sullivan (2013, p. 9) notes that "*a weir will function as broad crested when the width (aka breadth) exceeds twice the measured head*." Using a 2-inch check board as a broad crested weir provides a crest width of only 1.5 inches, which is less than one-half the typical measured head of 4.5 inches cited by Dr. Brockway, not two times the measured head.

3) Bos (1989) states that where a broad crested weir with ratio of H/L > 1.5, "*the nappe may separate completely from the crest and the weir in fact acts as a sharp crested weir. If H/L becomes larger than 1.5 the flow pattern becomes unstable and is very sensitive to the 'sharpness' of the upstream weir edge*". Column 7 of Tables 1-3 through 1-5 in Sullivan (2013) show that H/L (or H/B) for the Large, CTR and Lodge weirs is 1.5 or greater starting at a head of 3 inches. Mr. Sullivan also notes in his rebuttal report on page 9 that "when the measured head exceeds 1 to 2 times the width of the crest, the nappe will ordinarily spring clear and the weir will hydraulically operate as sharp-crested (Chow, 1964, King, 1976)."

4) Although Rangen has apparently used a rating table that more closely approximates a broad crested weir equation and coefficient, IDWR staff note that every annual measurement report submitted by Rangen to IDWR from 1995 through 2009 states that standard suppressed rectangular weirs are used (see Section III A of the IDWR annual report forms). Section III C of the IDWR annual report forms asks that copies of measuring device rating tables be attached to the report unless previously supplied to IDWR. None of the annual reports submitted to IDWR by Rangen include copies of rating tables used by Rangen. IDWR records do not show that the rating table identified in Appendix A of the December, 2012 Brockway report was received by IDWR until December 18, 2003. IDWR had assumed that Rangen was using standard rectangular suppressed weir tables from 1995 through 2002.

Tables 1-3 through 1-5 in Sullivan (2013) show computed discharges at the Large raceways, CTR raceways and the Lodge dam for what Mr. Sullivan calls "'*Hybrid Weirs' based on their function as broad crested weirs at low heads and sharp crested weirs at higher flows*." Also included in column 1 of Tables 1-3 through 1-5 are the corresponding discharges from the Rangen rating tables. As seen on page 11 of Sullivan (2013), the range of differences between the Hybrid Weir discharges and the Rangen rating

EXHIBIT "504"
Page No. 65 of 81

002012

table discharges is +0.8% to 10.2% for the Large Raceways, +1.1% to 10.9% for the CTR Raceways, and -6.4% to 20.2% for the Lodge Dam. Other than the Lodge Dam, the range of differences is within +/- 10 percent except for several head measurements on the Large Raceways with heads between 0.28 and 0.31 ft., where the differences are between 10.2% and 10.9%.

Column 8 of Tables 1-3 through 1-5 in Sullivan (2013) show the discharge coefficients used in Mr. Sullivan's Hybrid Weir equation. It is noted that for heads greater than 0.25 ft (3 inches), the coefficient is 3.32, or essentially the same as the coefficient used in the standard rectangular contracted and suppressed weir equations. Mr. Sullivan uses lower Hybrid Weir coefficients which approximate coefficients used for broad crested weirs for heads at 0.25 ft and less. It is important to note that head measurements above weir crests should exceed 0.2 ft. for sharp crested weirs as per USBR published guidelines (USBR, 1997). Use of a broad crested weir equation with coefficients of about 3.08 or 3.09 may be more appropriate for heads that measure 0.2 ft or less. At such heads, the ratio H/L is less than 1.50.

Based on review of the expert reports, IDWR staff provides the following opinions:

1. IDWR concurs with the Brockway (2013, p. 5) that the difference in weir coefficients between the standard suppressed rectangular weir with C=3.33 and use of the contracted rectangular weir with C=3.09 results in a difference of about 8%. IDWR also agrees with the statement on p. 9 of Brockway (2012), that "*the standard rectangular weir discharge using USBR weir flow calculations were within 8% of the Rangen staff reported flows*." (Note: The Rangen staff reported flows were -8% as compared to the same measurements using the USBR rating table for a standard contracted rectangular weir).

2. IDWR concurs with the Brockway rebuttal (2013, p. 5) that "standard weir formulas assume a sharp crested weir is in place and not a 2-inch board." However, the typical measured head at the Rangen raceways exceeds one to two times the 2-inch width weir crest such that the nappe separates from the crest and the weir more closely approximates a sharp crested weir where C = 3.33, which is the coefficient used with standard rectangular and suppressed weir equations.

3. IDWR concurs with both the Brockway (2013) and Sullivan (2013) rebuttal reports that the raceway check boards do not constitute standard suppressed rectangular weirs because the check boards are not sharp crested. It should also be noted that "*suppressed weirs must have proper ventilation of the cavity underneath their nappes. This ventilation is commonly done by installing properly sized pipes in the walls to vent the cavity under the nappe. Standard equations and tables are valid only when sufficient ventilation is provided. The weir will deliver more water than indicated by the tables and equations when ventilation is inadequate*." (USBR, 1997, p. 7-41).

4. IDWR concurs with the Brockway (2013, p. 5) that the differences in measurements between IDWR staff and Rangen staff are not due to differences in measurements of head at the weirs.

EXHIBIT "504"
Page No. 66 of 81

002013

IDWR concludes that the differences are due mostly to the use of different rating tables and weir coefficients.

5. IDWR does not concur with Brockway (2013, p. 5) that finds concern with IDWR's comparison of IDWR staff measurements with Rangen staff measurements "*because IDWR staff utilized the discharge rating curve for a standard sharp crested weir when in fact the flow was over dam boards, which is best represented by a modified weir coefficient resulting in a discharge rating similar to that utilized by Rangen personnel*." IDWR disagrees with this statement because the discharge rating used by Rangen uses coefficients that more closely approximate the standard coefficient used with a broad crested weir. As stated in item 2 above, the typical flow conditions for the Rangen check boards do not approximate conditions for a broad crested weir. Rather, typical flow conditions more closely resemble those for a rectangular sharp crested weir. IDWR maintains that without the installation of a standard measuring device, it is more appropriate to use the USBR sharp crested weir formula with a coefficient of 3.33 for estimating flows over the Rangen raceway check boards.

6. IDWR concurs with Sullivan (2013, p. 8) that the Rangen check boards do not conform to specifications of sharp crested weirs, contracted rectangular weirs, suppressed rectangular weirs or broad crested weirs. IDWR further concurs with Mr. Sullivan that use of the standard weir equation to compute flow does not result in the most accurate measurement of raceway discharges and that "it is appropriate to calibrate the weirs based on flow measurements to establish empirical rating tables that describe the relationship between discharge and measured head." However, IDWR continues to recommend the use of the standard suppressed weir equation at raceway check board dams with a coefficient of 3.33 since neither weir calibrations nor standard measurement devices exist at the Rangen Hatchery. If Mr. Sullivan recommends use of the Hybrid weir equation and coefficients, then IDWR notes that there is no difference in discharges between the Hybrid and standard suppressed weir equations for heads greater than 0.25 ft. Similarly, there is very little difference in discharge between the Hybrid Weir and the Rangen discharge tables for heads less than 0.25 ft (differences are between +0.8 to -6.8 % for CTR and Large Raceways).

7. IDWR does not concur with Sullivan (2013, p. 13) that the extent of under-measurement at the Rangen hatchery may be as high as 30 to 40 percent or more. SWE has not explained how or why the error may be this large unless they are merely adding the largest percent errors found in column 11 of Tables 1-3 through 1-5 for the CTR and Large Raceways, and the Lodge Dam, or they are merely relying on the example cited by the USBR in which a 0.1 ft. error in head measurement for a head of 0.45 ft. over a 6 ft. long rectangular weir results in an under-measurement of 2 cfs or 35 percent (USBR, 1997, p. 5-9). As described in these comments, the difference in head measurements between IDWR and Rangen staff on November 24 and November 25, 2003 appear to be relatively minor, and IDWR measured heads in a manner that minimized error.

EXHIBIT "504"
Page No. 67 of 81

8. IDWR accepted the measurements submitted by Rangen that are based on head measurements over raceway check boards and use of the Rangen rating tables because such measurements should be within a +/- 10 percent range of accuracy. The measurements likely under-measure actual flows, but an error up to -10% is acceptable pursuant to IDWR's *Minimum Acceptable Standards for Open Channel and Closed Conduit Measuring Devices.*

On page 13, Sullivan (2013) argues, "*The actual amount of any under-measurement of flow can be determined by conducting discharge measurements in the raceways and in Billingsley Creek using a current meter at various discharges to establish a calibrated rating table for each structure*." In the opinion of IDWR staff, it is difficult to obtain good, accurate measurements of discharge at or near the Rangen facility for calibrating the check board measurements, because flow and/or cross-sectional conditions are less than ideal. The USGS periodically measures the discharge in Billingsley Creek just downstream of the Rangen hatchery, but subjectively rates most of the measurements "fair" or "poor" indicating that USGS water measurement experts also found that flow and/or cross-sectional conditions in Billingsley Creek are not ideal and contribute to measurement error.

On page 14, Sullivan (2013) argues that "*under-measurement of the flows during the calibration period calls into question the model calibration to the Curren Spring flows, and would likely require that the model be re-calibrated*." The calibration target used for ESPAM2.1 was submitted to the ESHMC for review and comment in the fall of 2009. ESHMC members, including Mr. Sullivan and Dr. Brendecke, had more than two years to review the proposed calibration target and did not object to its use in ESPAM2.1. IDWR staff note that systematic under-measurement of discharge at the Rangen spring complex would be expected to result in lower model predictions of discharge and response to curtailment at the Rangen spring cell. This would favor the groundwater users, not Rangen.

On page 16, Sullivan (2013) points out that the ESHMC recommendation, "*The Eastern Snake Hydrologic Modeling Committee recommends that the Department begin using ESPAM Version 2.1 rather than ESPAM Version 1.1 for groundwater modeling*," was qualified by Mr. Sullivan and Dr. Brendecke with, "*although other tools or models may be more appropriate in certain circumstances*." IDWR staff note that neither Mr. Sullivan nor Dr. Brendecke proposed other tools or models that would be more appropriate for making a prediction in this circumstance.

ABSTRACT

The water resources of the eastern Snake River Plain are often at the forefront of water issues in Idaho. The Snake River Plain aquifer, underlying the eastern Snake River Plain, is hosted in layered basalts and interbedded sediments and is an integral part of the basin water resources. In some places, the flow of the Snake River is composed predominantly of aquifer discharge. Aquifer water levels and spring discharges increased through the first half of the century, but have been declining in the past several decades. The long-term changes are in response to changes in recharge and discharge associated with surface and ground-water irrigation. These changes are driving conjunctive management of surface and ground-water resources and the use of a numerical ground water model to understand and help manage the aquifer.

The University of Idaho and the Idaho Department of Water Resources developed a two-dimensional finite difference model of the Snake River Plain aquifer in the 1970s. That model has evolved into the model documented in this report. Most recently, the model has been adapted to use the U.S. Geological Survey's MODFLOW code and the domain has been expanded to include the northeastern part of the aquifer system. The model has been calibrated to a one-year period from April 1980 to March 1981. The transient calibration was conducted in two parts. The first part was the original model domain, calibrated by the Idaho Department of Water Resources. The second part, the area near and including the extended domain in the northeast, was calibrated by the University of Idaho. Extending the domain resulted in revisions to the model water budget and created a discrepancy between estimated recharge and discharge components. Further work should be performed to improve the model's reliability. Priority should be given to improving the conceptual understanding and quantitative behavior of the interaction with the Snake River.

INTRODUCTION

BACKGROUND

The water resources of the eastern Snake River Plain are often at the forefront of water issues in the State of Idaho. The high profile is due largely to intensive water use in the area by irrigated agriculture, hydropower, and aquaculture. These uses may sometimes be in conflict with environmental and recreation interests. This area is also underlain by the Snake River Plain aquifer (Figure 1), which is the water source for nearly all municipal and domestic needs in the area as well as for irrigation, aquaculture, and industrial needs.

Numerical ground-water flow models of the Snake River Plain aquifer have been developed and applied by state and federal agencies, universities, and private interests. The models vary in purpose, extent, and the computer code employed. The first numerical model of the aquifer was developed by the University of Idaho for the Idaho Department of Water Resources (IDWR) and the U.S. Bureau of Reclamation (deSonneville, 1974). The model has undergone multiple revisions and improvements. This report, together with Johnson and others (1999) documents another step in the evolution of the model.

The finite-difference model code developed by the University of Idaho and evolved by the University and the IDWR will be referred to as the IDWR/UI Ground Water Flow Model Code. The application of this code to the Snake River Plain aquifer

EXHIBIT "505"
Page No. 8 of 101

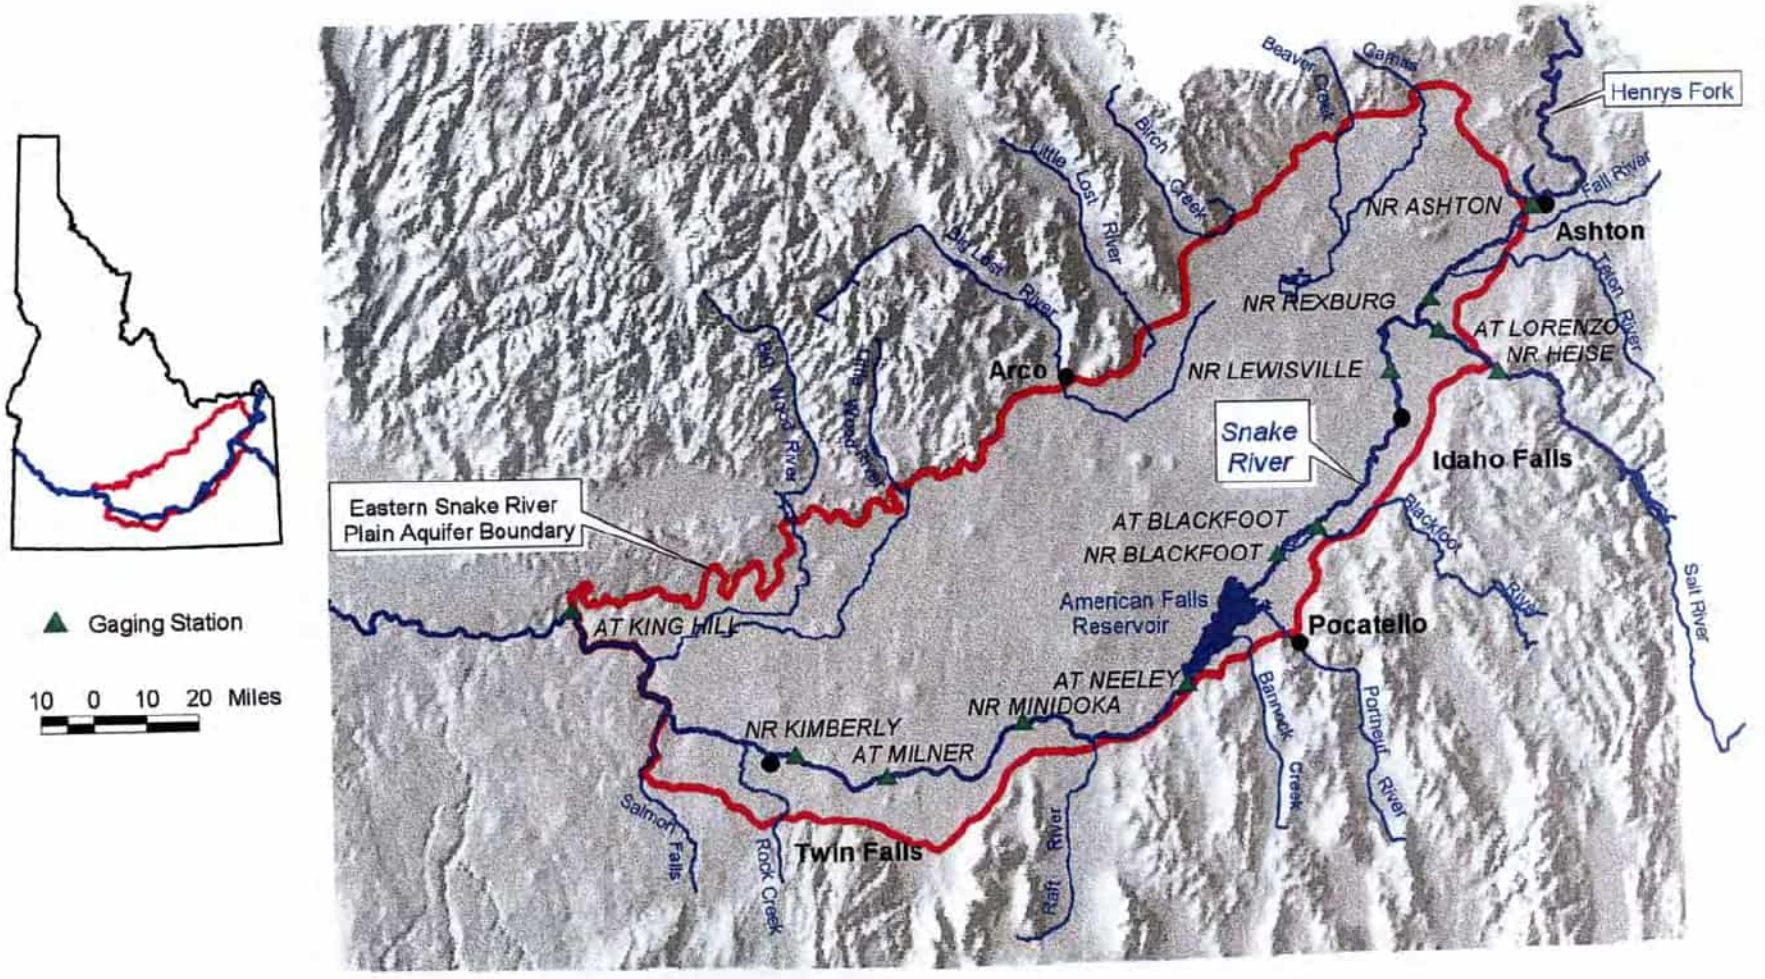

Figure 1. Snake River Plain Aquifer.

EXHIBIT "505"
Page No. 9 of 101

will be referred to as the IDWR/UI Ground Water Flow Model, following the convention established by the IDWR (IDWR, 1997). The IDWR has applied some version of this model as a planning and management tool for over two decades.

As part of this project, the IDWR/UI Ground Water Flow Model was converted to use one of the most widely used and accepted ground-water modeling codes, MODFLOW (McDonald and Harbaugh, 1988). The conversion to MODFLOW is not intended to create a new model, but to develop an equivalent model using a different code. The MODFLOW application to the Snake River Plain aquifer will be referred to as the Snake River Plain Aquifer Model (SRPAM), with the most recent version being SRPAM1.1. There are several benefits from conversion to the MODFLOW code including: a) the MODFLOW code is accepted as an industry standard, b) MODFLOW includes algorithms that simulate physical processes and have been verified against analytical solutions, c) MODFLOW is more familiar to a wider group of scientists and engineers, d) numerous user interfaces have been developed for MODFLOW, e) MODFLOW capabilities are continuously increasing, f) MODFLOW has a significant capability for treating more advanced features such as three-dimensional flow and variable grid spacing, and g) the MODFLOW code is well documented.

In addition to conversion of the IDWR/UI Ground Water Flow Model to the MODFLOW code, this project was established to improve model representation of the real system. This was achieved primarily by expansion of the model domain to include segments of the Snake River and tributaries in the northeast portion of the plain that were not previously simulated.

This report is one of two reports documenting work done on this project. This report provides a comprehensive documentation of the SRPAM1.1 model, along with comparisons between the SRPAM1.1 model and a model of the eastern Snake River Plain aquifer developed by the USGS during the 1980s, the USGS Snake River Plain Model. The reader should keep in mind that many of the assumptions made in early model development and evolution were not fully documented, so in many cases, this report records how the numerical model represents the physical system and not necessarily the rationale behind model design decisions. Detailed descriptions of model design decisions and calibration statistics from previous work are often not available. The *Recommendations* section addresses possible model enhancements to further improve the model. The companion report, "Conversion of the IDWR/UI Ground Water Flow Model to MODFLOW: The Snake River Plain Aquifer Model (SRPAM)" (Johnson and others, 1999), documents the conversion of the IDWR/UI Ground Water Flow Model to MODFLOW, the expansion of the model domain to include the Henrys Fork and South Fork region, and the localized calibration of the extended model.

These reports are the result of a combined effort of the U.S. Bureau of Reclamation, the University of Idaho, and the Idaho Department of Water Resources. The model described in the reports is intended to be a planning and management tool for use by both agencies. It is also intended that the model will evolve as further fiscal and data resources become available. Model refinements are suggested in the section on *Recommendations For Future Work*. The U.S. Bureau of Reclamation's Snake River Resources Review program provided funding for this project.

PURPOSE AND SCOPE

The purpose of this project was to improve capabilities and documentation of the IDWR/UI Ground Water Flow Model. Objectives include:

1) Conversion of the model to a more widely used and versatile code that will readily accommodate future enhancements,
2) Verification that model conversion creates no significant changes in model results,
3) Modification of the model to include those refinements deemed most significant to the predictive capabilities on a regional scale,
4) Providing the IDWR and USBR with a model that both agencies accept as suitable for planning and management,
5) Improve model documentation.

This project was conducted as part of the U.S. Bureau of Reclamation's Snake River Resources Review. The Snake River Resources Review project is attempting to define all of the interests in the Snake River and develop models that will describe the impact of river operation options on the various interests. The inclusion of ground water components in the program is a response to the increasing awareness of the interaction of ground water and surface water. The model described in these reports will be used subsequently to develop analytical expressions (response functions) relating aquifer recharge and discharge at specific locations to spring discharge and flow in the Snake River. It is anticipated that these relationships will become elements of the array of water management tools forming the decision support system being developed under the Snake River Resources Review program. These products also will provide a means to further

educate the public on surface and ground water relationships and assist in the development of mitigation plans between ground water and surface water users.

The IDWR's use of this model will be primarily for planning and management of the Snake River Plain aquifer. Increased ground water pumping and changes in surface irrigation practices in the last few decades have caused declines in ground-water levels and spring flows, sometimes impacting more senior surface water rights. The Department will increasingly be called upon to arbitrate in conjunctive management disputes and evaluate mitigation plans. The Department also is engaged in planning managed recharge efforts on the Snake River Plain. The model resulting from this effort, the Snake River Plain Aquifer Model (SRPAM) will be one of the tools employed to resolve these problems.

DESCRIPTION OF THE SNAKE RIVER PLAIN AQUIFER

GENERAL FEATURES

The Snake River Plain extends in an arcuate shape across most of southern Idaho and into eastern Oregon. The plain is divided into eastern and western portions based primarily on ground-water hydrology. The eastern Snake River Plain is the focus of this report and occupies an area of about 10,000 square miles extending northeast from King Hill to near Ashton (Figure 1). The boundaries of the plain, shown in Figure 1, were defined by the U.S. Geological Survey's Regional Aquifer- System Analysis (RASA) program (Lindholm, 1993). Elevation of the eastern plain varies from about 2600 feet above sea level in the southwest to over 5000 feet in the northeast.

Population within the plain is generally sparse, with most of the population residing along the eastern and southern margins of the plain in an agriculturally productive band near the Snake River. Much of the remainder of the plain is federal land managed primarily by the U.S. Bureau of Land Management. Portions of the plain are covered by rugged basalt outcroppings that include the Craters of the Moon National Monument.

The Snake River Plain enjoys an arid to semi-arid temperate climate. Precipitation ranges from about 8 to 14 inches per year, falling predominantly in the colder months. Irrigation is required for agricultural production. The crops grown vary with location; the major crops throughout the plain include potatoes, wheat, barley,

alfalfa, and sugar beets. Dry edible beans and peas are grown in the southwestern part of the valley.

Irrigation on the eastern Snake River Plain began in the late 1800s using water from the Snake River and its tributaries. Garabedian (1992) describes changes in surface-water and ground-water irrigated areas on the eastern Snake River Plain that are shown graphically in Figure 2. Acreage irrigated by surface water has been declining since the mid-1940s. Since the onset of ground-water irrigation in the 1950s, the number of acres irrigated by ground water has been increasing steadily.

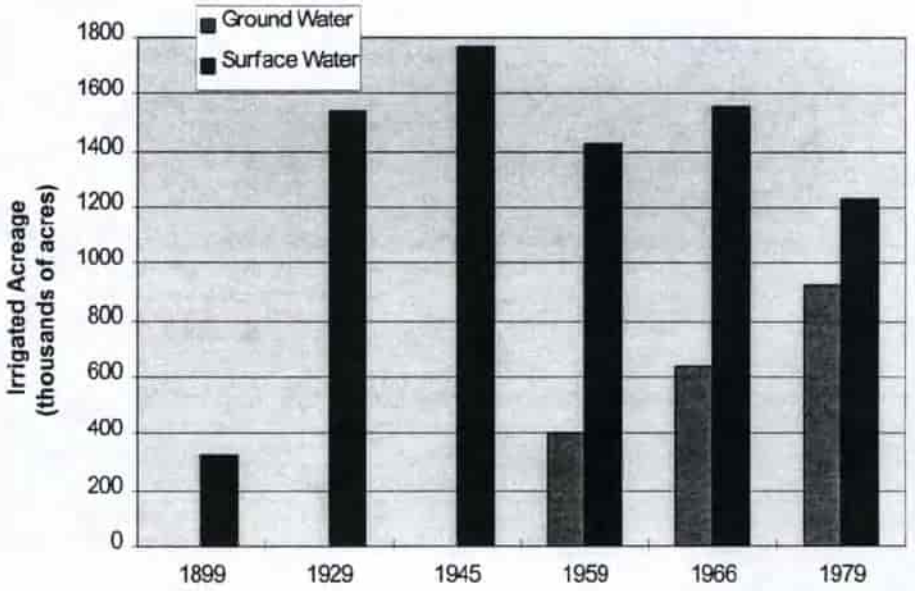

Figure 2. Changes in Surface and Ground Water Irrigated Acres on the eastern Snake River Plain. (After Garabedian, 1992.)

Irrigation practices are continually changing in response to technology and economic factors. Furrow, flood, and sub-irrigation were the dominant methods of water application into the second half of the twentieth century. In the 1980s and 1990s

sprinklers commonly have replaced surface application methods, with a resulting decrease in the amount of water diverted per acre of agricultural land.

Recent changes in Idaho water law have dramatically affected water use and expansion of irrigation development on the Snake River Plain. A basin-wide adjudication of water rights was initiated in 1992 (Idaho Water Resources Board, 1996). Expansions of irrigated acreage before 1987 that were not within the requirements of the Prior Appropriation Doctrine were forgiven in legislation passed in 1996. A moratorium on expansion of irrigated acreage has been in effect for the Snake River Basin since 1992. The moratorium includes both surface and ground water irrigated lands within the basin (Idaho Water Resource Board, 1996). Conjunctive management rules were promulgated by the IDWR in 1996, essentially linking administration of ground and surface water right priorities. Water measurement districts were established in 1997 to provide records of ground-water pumpage for irrigation. Managed recharge of the Snake River Plain aquifer has been supported by the Idaho Legislature. Managed recharge, which has occurred at various locations through existing irrigation facilities, was estimated at 180,000 acre-ft (AF) in 1995, 169,000 AF in 1996, and 230,000 AF in 1997 (Idaho Water District #1 records).

GEOLOGIC SETTING

The surface of the Snake River Plain consists primarily of volcanic rocks, which, in most areas, are covered by a veneer of windblown or fluvial sediments. Exposed volcanic rocks are predominantly basalt, which in places such as the Craters of the Moon

National Monument, cover expansive areas. Sediment deposits overlying the basalt vary in thickness from zero to tens of feet.

The eastern Snake River Plain is composed of a series of relatively thin basalt flows and interbedded sediments. Flows range in thickness from a few feet to tens of feet. Welhan and Funderberg (1997) report median flow thickness near the Idaho National Engineering and Environmental Laboratory ranging from about 7 to 25 feet. Individual flows typically have a rubble or clinker zone at the top and bottom with a more massive interior containing fewer vesicles. Vertical fractures in the flow interiors form columnar basalt in places (Garabedian, 1992). Individual basalt flows generally are not areally extensive (Welhan and Funderberg, 1997). The collective thickness of basalt flows of the eastern Snake River Plain are estimated to exceed several thousand feet in places (Whitehead, 1986). More detailed descriptions of the geology of the eastern Snake River Plain are provided by Anderson (1991), Whitehead (1986), and Kuntz and others (1992).

The eastern plain is bounded structurally by faulting on the northwest and downwarping and faulting on the southeast (Whitehead, 1986). The plain is bounded by Yellowstone Group rhyolite in the northeast and Idavada volcanics in the southwest. Granitic rocks of the Idaho batholith, along with pre-Cretaceous sedimentary and metamorphic rocks, border the plain to the northwest (Garabedian, 1992).

SURFACE-WATER HYDROLOGY

The Snake River passes along the southern margin of the eastern Snake River Plain and is the exclusive surface water discharge mechanism for the eastern plain.

Ground water underflow out of the eastern plain is assumed to be minimal, making the flow of the Snake River at King Hill the approximate equivalent of basin discharge, excluding evaporation. Annual discharge of the Snake River at King Hill is shown in Figure 3. The cumulative discharge line in Figure 3 shows little change in slope. This indicates that despite significant changes in water use during the last several decades, there has been little change in basin outflow. A possible reason for the stability of the slope of the cumulative graph in Figure 3 is that human activities have apparently had a greater temporary impact on aquifer storage than on basin outflow.

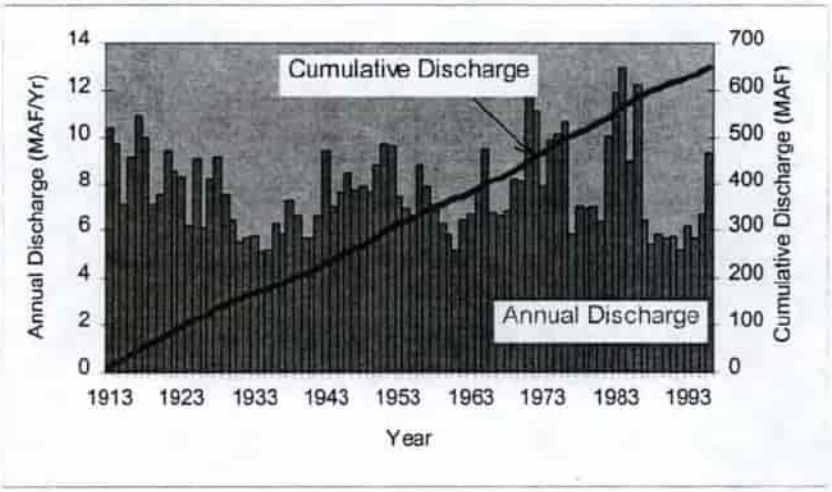

Figure 3. Annual and Cumulative Discharge of the Snake River near King Hill (U.S. Geological Survey data).

The Snake River is intensively managed for irrigation and hydropower generation. The average annual flow, major inflows and diversions at different points within the system are illustrated by river width in Figure 4. The flow in the Snake River is noticeably depleted at Milner Dam where substantial diversions are made for irrigation. A gradual increase in river flow below Milner Dam is due largely to aquifer discharge in

the form of springs emitting from the wall of the Snake River canyon. North of Idaho Falls, in the eastern part of the plain, the Henrys Fork (locally referred to as the North Fork) joins the Snake River, locally referred to as the South Fork, shortly downstream from Lorenzo. The origin of the Henrys Fork is in the Island Park area to the northeast of the Snake River Plain. Headwaters of the Snake River are in Yellowstone Park in Wyoming. On average, yield of the Snake River at Lorenzo is about twice the yield of the Henrys Fork near Rexburg.

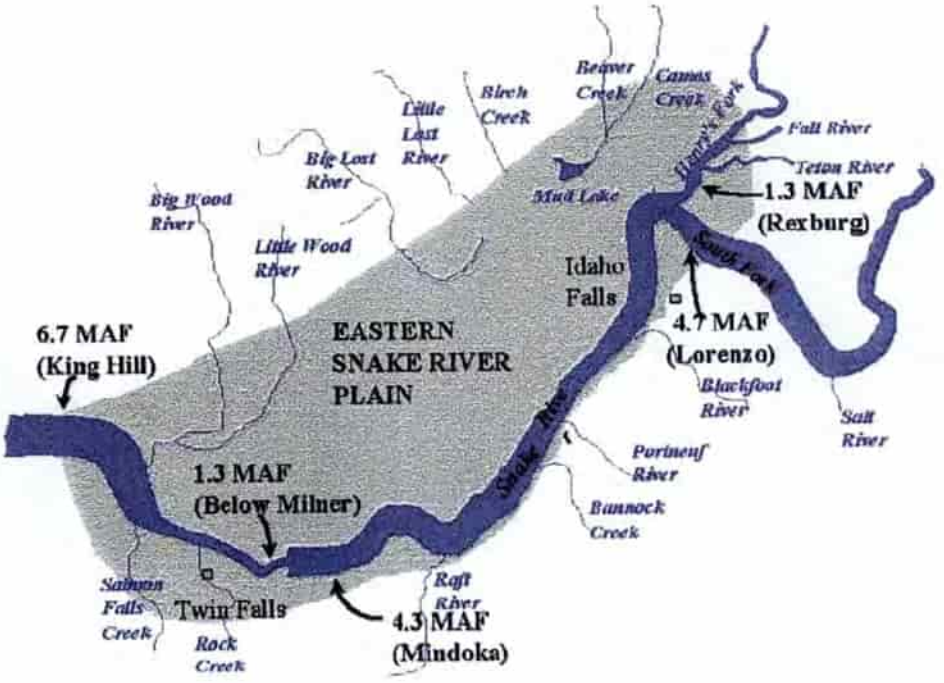

Figure 4. Conceptual Illustration of Variation in Average Annual Flow of the Snake River (after the U.S. Bureau of Reclamation, 1996).

Several reservoirs have been constructed on the Snake River and its tributaries for the purposes of irrigation, flood control, hydropower generation, and recreation. In some

years, spring snowmelt exceeds system storage capacity and irrigation demands and water is spilled past Milner Dam. On average, about two million AF of water are discharged annually past Milner Dam (Figure 5). Some of this discharge is provided to meet downstream water rights and environmental needs.

Direct tributaries to the Snake River occur primarily from the east and south sides of the basin. Several streams along the northern margin disappear through seepage before flows can reach the Snake River (Figure 4). Only flows of the Big and Little Wood Rivers, Silver Creek, and Camas Creek may eventually reach the Snake River from the northern margin of the plain. Other streams on the northern margin of the plain, such as the Big and Little Lost Rivers, contribute recharge to the Snake River Plain aquifer, but do not directly discharge to the Snake River.

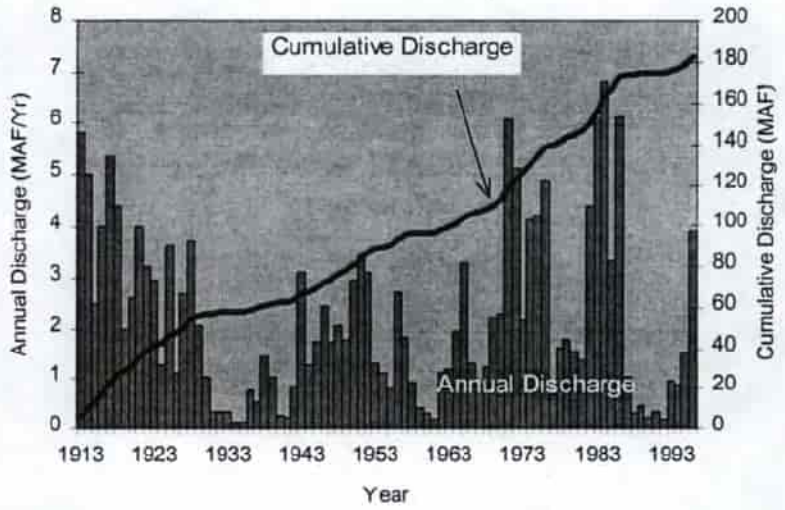

Figure 5. Historic Discharge of the Snake River at Milner Dam (U.S. Geological Survey Data).

An extensive network of irrigation canals provides water for over one million acres of irrigated land on the eastern Snake River Plain. Different reports provide

different estimates of surface water irrigated land due to: 1) differences in the area being evaluated, 2) difficulties discriminating between ground-water and surface-water irrigated land in some places, and 3) the application of adjustments for non-productive lands (e.g. homesteads, roads, ditches) within an area that appears irrigated in satellite images. In 1980, the U.S. Geological Survey reported 2.1 million acres of irrigated land on the eastern Snake River Plain (Garabedian, 1992) within the boundaries shown in Figure 1. The IDWR estimated 1.4 million acres of irrigated land in 1992 (IWDR, 1997); however, the IDWR estimate did not include the south side of the Snake River near Twin Falls, nor most of the Henrys Fork area, which accounts for several hundred thousand acres.

Irrigation diversions consume a large proportion of the flow of the Snake River during irrigation season. Diversions of surface water for irrigation in the eastern Snake River Plain (including all tributaries) have diminished by about 20 percent from the nearly eight million AF/yr diverted in the early 1970s (see IDWR, 1997, Figure 16). Irrigation diversions have a significant impact on flow of the river; however, some of the diverted water returns to the river as either surface or ground water return flows. In addition, surface water diverted for irrigation also has a major effect on recharge of the Snake River Plain aquifer as will be discussed in the following section.

GROUND-WATER HYDROLOGY

The Snake River Plain aquifer underlies the eastern Snake River Plain. This highly productive aquifer is hosted in fractured basalts and interbedded sediments. The primary conduit for ground-water flow appears to be the highly permeable rubble zones

that formed at the tops of the numerous basalt flows which comprise the Snake River Plain. Garabedian (1992) reports median specific capacity on a county basis for 176 wells across the eastern plain. The median values ranged from 4 to 950 gallons per minute per foot of drawdown, with the largest values occurring in counties near the center of the plain where Quaternary basalts are thickest. The lower values were found near the margins of the plain where Tertiary basalts and sediments predominate.

Although the collective thickness of the basalt flows may be in excess of several thousand feet in places, the active portion of the aquifer often is thought to be limited to the upper several hundred feet of saturated thickness. Robertson (1974) states that "Although the real aquifer system is probably more than 1,000 feet thick, a thickness of 250 feet is used in this study based on the apparent layering effects of the aquifer." Based on the presence of low permeability sedimentary layers encountered in a well drilled on the Idaho National Engineering and Environmental Laboratory, Mann (1986) suggests that the aquifer is 450-800 feet thick. Model studies by the U.S. Geological Survey (Garabedian, 1992) represent the aquifer as four layers with a collective thickness ranging from 500 to over 3,000 feet. Modeling by the IDWR and the University of Idaho (deSonneville, 1974; Newton, 1978; IDWR, 1997) represents the aquifer as a single layer ranging from 200 to 1,700 feet thick.

The Snake River Plain aquifer generally is considered unconfined; however, in some locations and under certain conditions the aquifer responds as a confined system. In some areas, low permeability lakebed sediments create local confining layers (Spinazola, 1994). The layered basalts and interbedded sediments also may produce

conditions that appear locally confined, at least when subjected to short duration stress (Frederick and Johnson, 1996).

The Snake River Plain aquifer is recharged by irrigation percolation; canal, stream, and river losses; subsurface flow from tributary valleys; and precipitation directly on the plain. The aquifer discharges to the Snake River, to Snake River tributaries, springs along the Snake River and to ground-water pumping, primarily for irrigation. The relative magnitudes of the recharge and discharge components were evaluated by the USGS (Garabedian, 1992) and, more recently, by the IDWR (1997). Estimates from the USGS represent conditions in 1980 for the entire Snake River Plain (Figure 6). Estimates from the IDWR represent a projection to near equilibrium conditions (e.g. negligible change in storage) with the level of irrigation development that existed in 1992 (Figure 7). The IDWR work applied weather conditions that were averaged for 1950 to1981 and surface water diversions that were averaged for the period of 1982 to 1992. In the context of this report, evapotranspiration (ET) is used to describe the consumption of water by agricultural crops and not ground-water discharge via stream-bank or wetland plants. The USGS estimates include portions of the plain not included in the IDWR estimate due to differences in model boundaries (model extent is discussed in a later section). A comparison of Figures 6 and 7 shows several components (ET, pumpage and canal losses) which are explicitly shown in one of the water budget analyses but are embedded within other components in the other analysis. This is due to different presentation selections for the two water budgets. All of the components have been accounted for in both of the water budgets.

Incidental aquifer recharge from irrigation is a significant component of the water budget and has varied as irrigation practices have evolved. The 1980 water budget of the USGS (Garabedian, 1992), shown in Figure 6, shows that surface water irrigation contributes more than 50 percent of the total recharge to the aquifer. Historically, recharge from surface water irrigation increased as more land was brought into production up to the 1970s. Since the 1970s, a gradual conversion to sprinkler irrigation methods reduced the amount of incidental recharge from irrigation. In addition, ground-water use for irrigation has increased during the past several decades.

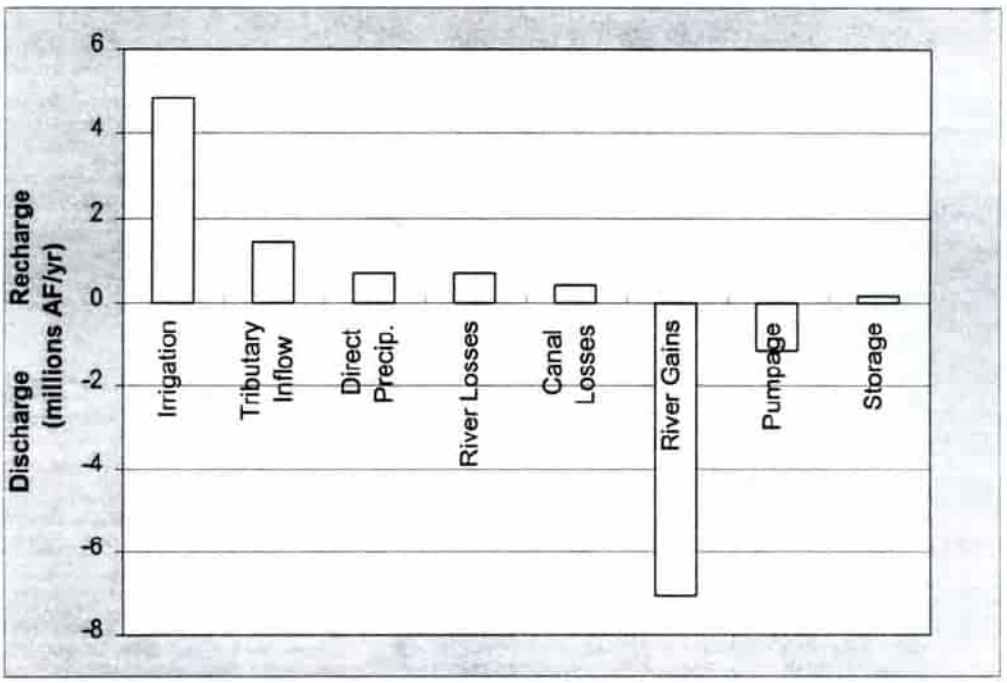

Figure 6. Snake River Plain Aquifer Estimated Annual Recharge and Discharge from April 1980 through March 1981 (after Garabedian, 1992).

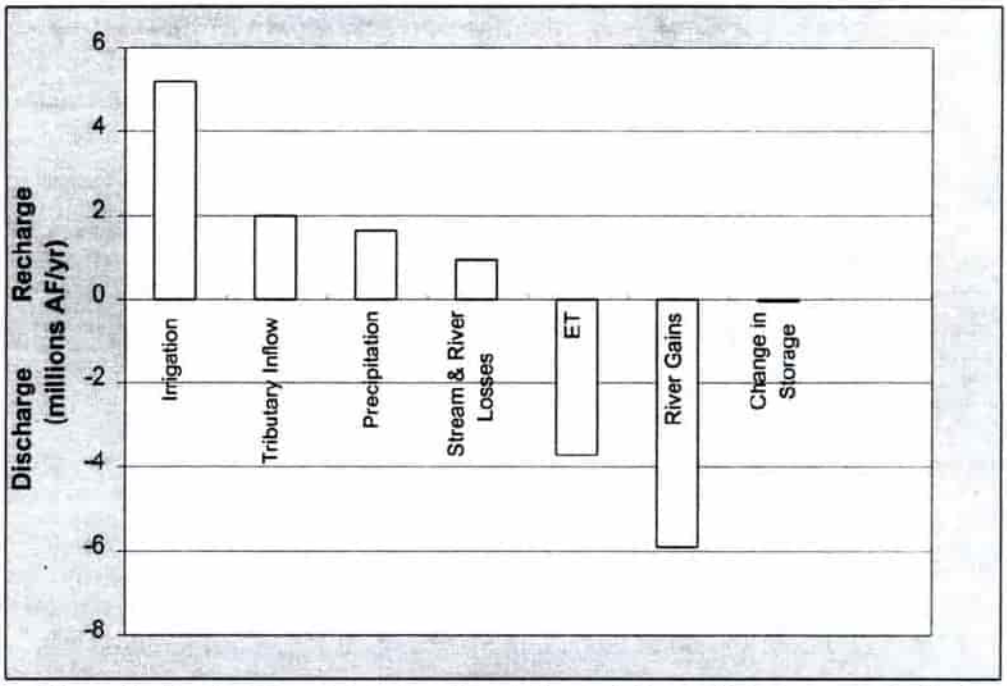

Figure 7. Snake River Plain Aquifer Estimated Annual Recharge and Discharge Assuming the Irrigation Development Level of 1992 and Near Equilibrium Conditions in the Aquifer (after IDWR, 1997).

Natural discharge from the Snake River Plain aquifer is primarily to the Snake River along two reaches: Kimberly to King Hill, and Blackfoot to Neeley. These reaches are defined by gaging stations shown in Figure 1. Spring discharge has varied in response to changes in weather, irrigated acreage, and irrigation practices. Discharge in the Kimberly to King Hill reach appears to have been impacted more than in the Blackfoot to Neeley reach (Figure 8). The effects of weather variation and irrigation recharge are apparent from the short-term variation of spring discharge. Maximum discharge occurs around October, near the end of irrigation season. The seasonal variation in the Blackfoot to Neeley and Milner to King Hill reaches is about 15 and 20 percent of the respective maximum reach gains (from interpretation of Kjelstrom, 1995).

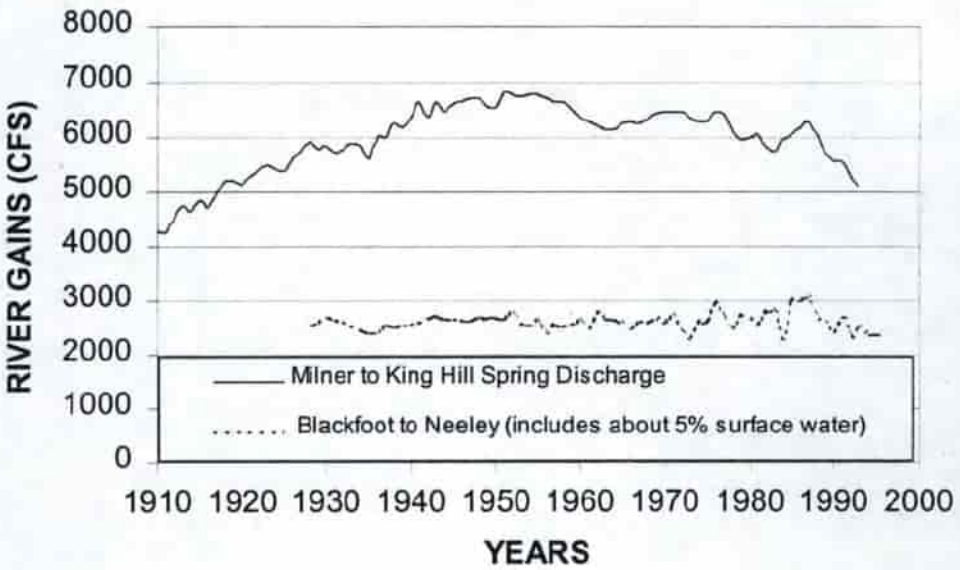

Figure 8. Average Annual Snake River Gains in the Milner to King Hill and Blackfoot to Neeley Segments. (From IDWR data.)

Other reaches of the Snake River also are hydraulically connected to the aquifer. In these segments, the river may gain or lose water, depending on river stage and the water level in the aquifer. The Neeley to Minidoka reach both gains and loses water, with gains generally exceeding losses. Further upstream, between Heise and Lorenzo, the South Fork of the Snake River is a seasonally losing stream (Kjelstrom, 1995). Average annual loss of this reach was 150 cfs in the 1980 water year. During that same period, the Lorenzo to Lewisville reach of the main stem of the Snake River and the lower Henrys Fork reach were estimated to have gained 290 and 120 cfs, respectively (Garabedian, 1992).

Contours of the potentiometric surface indicate that ground-water flow direction generally is parallel to the axis of the plain (Figure 9). Steep hydraulic gradients are apparent near the margins of the plain due to tributary valley inflow and lower transmissivity relative to the center of the plain. Steep gradients also are apparent near the Kimberly to King Hill discharge area due to convergence of flow lines and probable aquifer thinning. Near the center of the plain and near Mud Lake, steeper gradients presumably result from decreased transmissivity due to the volcanic rift zone and thick sediment deposits, respectively.

Aquifer water levels have changed significantly over the past several decades in response to changes in irrigation and variations in weather (Figure 10). The greatest changes in water level appear in a band traversing the south-central portion of the plain. Water level declines between 1980 and 1996 are as large as 15 feet in this area. Some portions of the Snake River Plain aquifer have experienced little decline or slight increases in water level.

SRPAM1.1 MODEL DESCRIPTION

This section provides a consolidated description of the SRPAM1.1 model. A brief model history is presented. The model grid and boundaries are described, including the representation of rivers, tributary valley underflow and aquifer bottom, recharge and discharge, and aquifer properties. The appendix contains comparisons between the SRPAM1.1 model and the USGS Snake River Plain Model (Garabedian, 1992) to provide an understanding of the degree to which model construction and input are affected by interpretation and methods of the modeler.

BRIEF MODEL HISTORY

The first numerical model of the aquifer was developed by the University of Idaho for the Idaho Department of Water Resources (IDWR) and the U.S. Bureau of Reclamation (deSonneville, 1974). The model has undergone multiple revisions and improvements. The IDWR has applied some version of this model as a planning and management tool for over two decades. For the past decade, the model has been referred to as the IDWR/UI Ground Water Flow Model. As part of this project, the IDWR/UI Ground Water Flow Model was converted to use the MODFLOW code and the model domain was expanded to include the Henrys Fork and South Fork of the Snake River (Johnson and others, 1999). The converted and expanded model, referred to as SRPAM1.1, is the model documented in this report.

MODEL FEATURES

MODFLOW Packages Used in SRPAM1.1

The SRPAM1.1 implementation uses six MODFLOW packages: the BAS package, the BCF3 package, the Well package, the River package, the SIP package and the Output Control Package. The SRPAM implementation of these packages is briefly described below.

- The MODFLOW Basic Package contains grid and time characteristics of the model and the starting head array.
- The MODFLOW BCF3 input contains aquifer bottom, hydraulic conductivity, and specific yield arrays. Input in this file also sets the model domain as unconfined and applies the logarithmic interblock transmissivity averaging.
- The MODFLOW Well Package is used to represent the net recharge and discharge (non-head dependent) to each cell. The net recharge is determined using the RECHARGE Program (Johnson and Brockway, 1983). All recharge/discharge due to precipitation, canal seepage, tributary underflow, irrigation application, evapotranspiration and groundwater withdrawals is calculated for each model cell in the RECHARGE Program. The net recharge/discharge for each model cell is then represented as an injection or withdrawal from the aquifer using the MODFLOW Well package.
- The MODFLOW River Package is used to simulate those reaches of the Snake River that are modeled as head-dependent, as described above.
- The MODFLOW SIP Package was selected as the numerical solver. The closure criterion was set at 0.01 feet.

- A MODFLOW Output Control file is used to acquire the detailed output at specified stress periods.

Inter-block transmissivities in the SRPAM1.1 model are averaged using a logarithmic mean. In contrast, most other model applications use the harmonic mean for interblock averaging of transmissivity. The harmonic mean was the only option available in the original version of MODFLOW. MODFLOW routines have been modified in recent years, however, to include an optional logarithmic averaging method (Goode and Appel, 1992) identical to that employed by IDWR/UI Ground Water Flow Model. The revision is included in the BCF3 package that replaces the original MODFLOW BCF package (LAYAVG=20, LAYCON=21).

Model Grid

The SRPAM1.1 model grid consists of one unconfined layer of uniform 3.1 mile (5 km) square grid cells with 48 rows, numbered progressively from south to north, and 63 columns, numbered from west to east (Figure 11). The origin, in the southwest corner of the grid, is at latitude 42.28721696° and longitude 115.19637586° (location of the southwest corner of model cell 1,1). The Universal Transverse Mercator (UTM) zone 12 grid coordinates of the origin are a northing of 4,689,986.00 meters by an easting of 153,994.094 meters. The grid columns are oriented parallel to the central meridian of UTM Zone 12 (111°00'00"). SRPAM1.1 uses a block-centered grid with node points in the center of cells.

Model Boundaries and Tributary Underflow

Model boundaries include no flow and specified-flux (underflow) along the margins of the plain and a head-dependent representation of some segments of the Snake River. Specified flux boundaries are used to represent underflow from surrounding tributary valleys including the Big Lost River, the Little Lost River, Warm Springs Creek, Deep Creek, Medicine Lodge Creek, Beaver Creek and Camas Creek, the Teton River, Big Bend Ridge, the Rexburg Bench, the South Fork of the Snake River, and the Portneuf River. Figure 12 shows the locations of model cells containing specified flux values representing underflow at tributaries. Table 1 lists the tributaries represented in SRPAM1.1 model (for the 1980 calibration year) and those used in the U.S. Geological Survey model (Garabedian, 1992) is presented in the Appendix. Specified flux is incorporated into the net recharge for each boundary cell with modeled underflow in the RECHARGE Program (Johnson and Brockway, 1983) which is described in the section *Calculation of Recharge and Discharge for SRPAM1.1*. Tributary valley specified flux is modeled as time-invariant; that is, the underflow values are constant throughout the entire simulation.

Representation of River Reaches

Some segments of the Snake River are treated as head-dependent flux boundaries, while others are represented as specified flux boundaries with recharge rates specified as input to the RECHARGE Program. The RECHARGE Program is not interactive with the

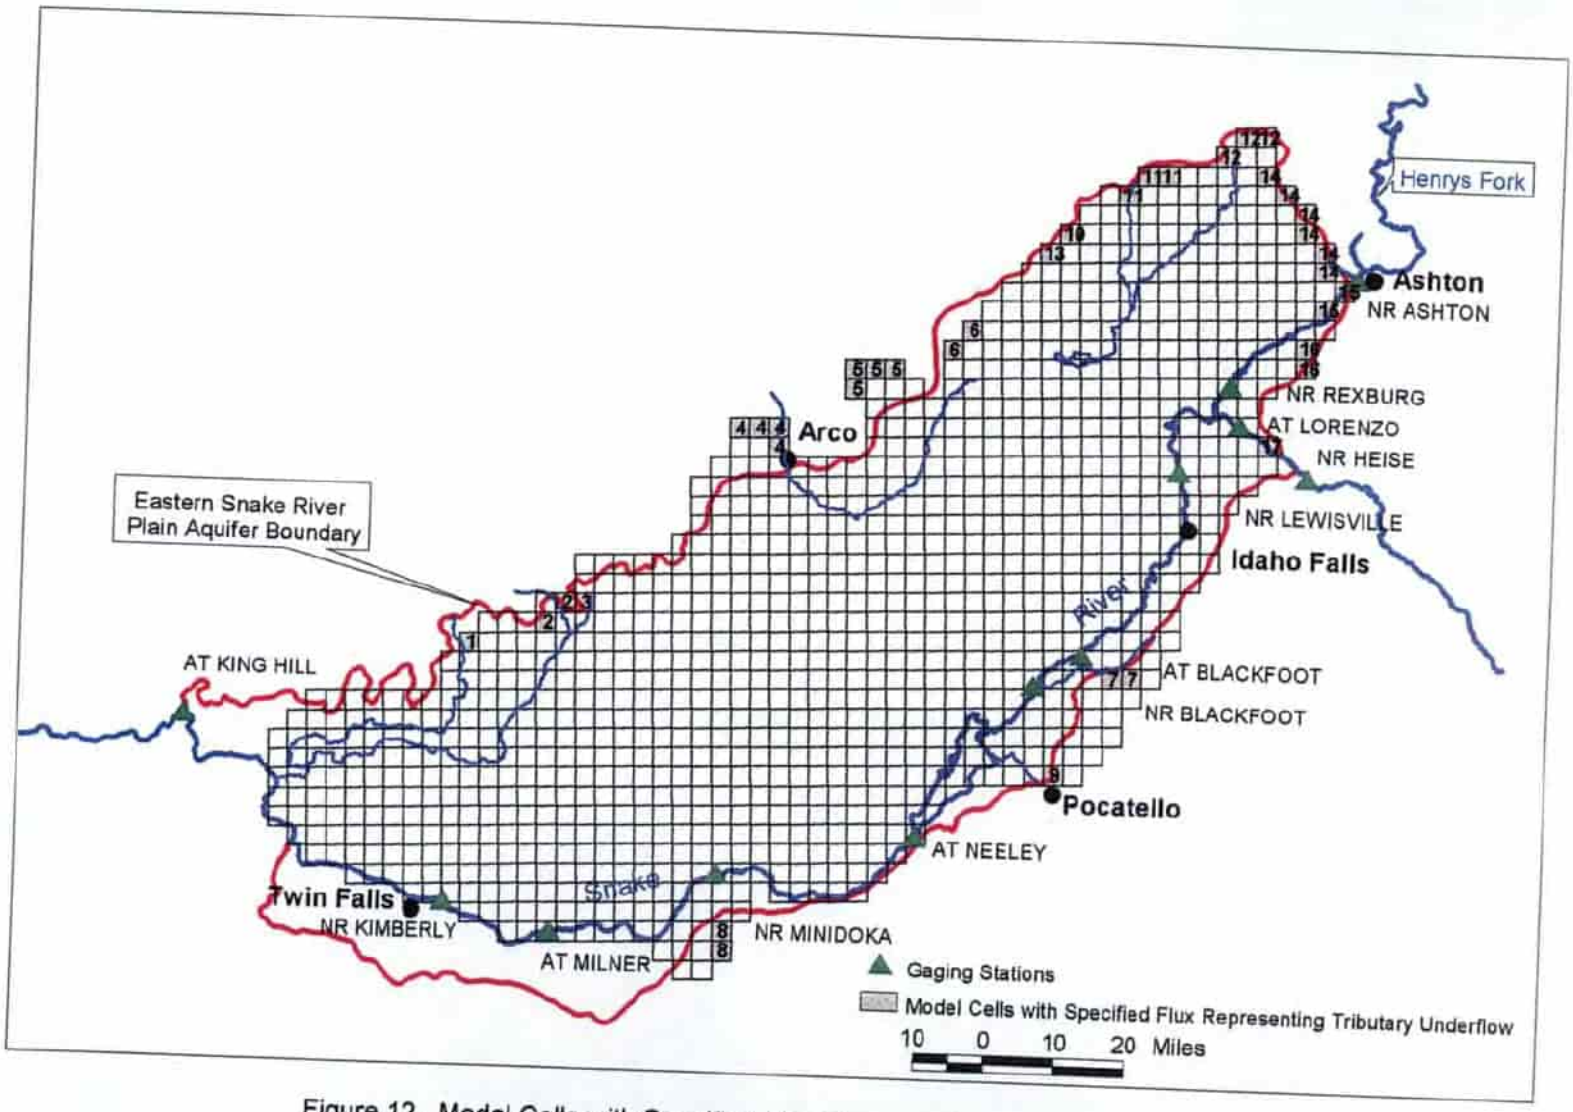

Figure 12. Model Cells with Specified Flux Representing Tributary Underflows.
(Note: Specified Flux Cell Numbers are cited in Table 1.)

ground water model, therefore only recharge and discharge components that are independent of aquifer head can be included in the RECHARGE Program calculations.

Non-head dependent, or perched, river segments are simulated in the Lewisville to Blackfoot and the Minidoka to Kimberly segments of the Snake River. In these segments, river losses are considered independent of aquifer head and are specified as time-variant input to the RECHARGE Program. The estimated magnitude of the river

losses for the model calibration year are discussed in the section *Calculation of Recharge and Discharge for SRPAM1.1*. The assumption that these reaches are independent of aquifer water level is a simplifying assumption. Kjelstrom (1995) indicates that seepage in these reaches is to some degree dependent on aquifer water levels. However, the relatively small gains and losses in these reaches may have justified the simplifying assumption at the time the model was developed.

Head dependent, or hydraulically connected, river representation was limited to specific segments of the Snake River shown in Figure 11. Those segments, as bounded by gaging stations include:

Henrys Fork from Ashton to Rexburg
South Fork from Heise to Lorenzo
Henrys Fork (from Rexburg) and South Fork (from Lorenzo) to Lewisville
At Blackfoot to Neeley
Neeley to Minidoka
Kimberly to King Hill

In these river segments, simulated river gains and/or losses are partially controlled by simulated water-table elevations. Other features such as Camas Creek and Mud Lake may be in hydraulic communication with the aquifer but have not been represented as head-dependent features in the model.

Simulated river gains and losses in head-dependent river segments are controlled by input values of river stage, riverbed conductance, and elevation of riverbed bottom (for details see McDonald and Harbaugh, 1988). The values input for these items vary with location.

In the Kimberly to King Hill river segment, the river stage is used to represent average elevations of springs along the canyon wall. A very high aquifer stress in this area could cause water levels to drop sufficiently to cause a reversal in the direction of

spring flow. Although such a large change in aquifer water levels is unlikely, the representation of springs in this area should be considered for modification in future versions of the model. In other segments the river stage is representative of the elevation of the river surface. In the Blackfoot to Neeley segment, river stage is simulated as time-variant during the 1980 calibration year. This was probably done to reflect high fluctuations in river stage due to operations at American Falls Dam. In all other segments, river stage is less variable and, therefore, is simulated as a constant value representing a time-averaged water level.

River conductance is a term used to represent the collective effects of river dimensions within a model cell and the hydraulic conductivity of riverbed and bank materials. In SRPAM1.1, river conductance is set to an arbitrarily large value in all river segments below Blackfoot. This results in river gains and losses being controlled by hydraulic conductivity of the model cells in which the river is represented. This was done to maintain consistency with earlier model versions (see Johnson and others, 1999 for more detail). In the river reaches upstream from Lewisville, including the Henrys Fork and South Fork, river conductance was calibrated to reproduce estimated river gains and losses during the calibration year.

Riverbed bottom elevation is a threshold where a river transitions between hydraulically connected and perched. In earlier model versions, the river reaches below Blackfoot were modeled as fixed head. By using a high river conductance value and a low river bottom elevation for these river reaches, the river gains simulated with the SRPAM1.1 version were consistent with the river gains simulated in earlier model

versions. In the river reaches above Lewisville, the riverbed bottom elevation is set to about 30 feet below river stage.

Aquifer Bottom

The aquifer bottom was modeled at a uniform elevation of 3100' above sea level throughout most of the SRPAM1.1 model area. In the model cells approaching the Kimberly to King Hill segment of the Snake River, the modeled elevation of the aquifer bottom slopes gradually to approximately 2550' elevation. This slope in elevation is effected across approximately six model cells or 19 miles. This configuration was adapted to be consistent with the IDWR/UI Ground Water Flow Model. Reliable data on the elevation of the bottom of the aquifer were not available when the model was developed, so the choice of the elevation of the bottom of the aquifer was somewhat arbitrary. The uniform elevation of 3100' feet was probably selected to be lower than the deepest known wells in the aquifer. During the model calibration, the hydraulic conductivities would have compensated for the unknown saturated thickness to achieve the desired simulated water levels.

MODEL CALIBRATION

The SRPAM1.1 model contains a combination of aquifer parameters previously calibrated for the IDWR/UI Ground Water Flow Model and aquifer properties calibrated during a localized calibration of the expanded model area (grayed cells in Figure 11) during the conversion to SRPAM1.1. Both areas were calibrated to transient conditions for the April 1, 1980 through March 31, 1981 period, using 24 stress periods of 15.2 days.

The model domain of the IDWR/UI Ground Water Flow model was calibrated and documented most recently in IDWR (1997). An automatic calibration routine was used to assist in the calibration of transmissivity and specific yield in the original model domain. Comparisons between simulated and measured values of aquifer head were made in the 11th (mid September) and 24th (end of March) stress periods. The calibrated aquifer properties were carried forward during the conversion to SRPAM1.1.

A localized calibration of hydraulic conductivities and specific yields in the expanded model area (the Henrys/South Fork region) was done as part of the conversion to SRPAM1.1. As part of the localized calibration of the Henrys/South Fork area, aquifer properties in the original model domain in the extreme northeast portion of the original model also were changed. Model cells approximately 6 rows into the original model domain were re-calibrated along with model cells in the expanded portion of the model. Additionally, river conductances in the expanded model domain were calibrated as part of the localized calibration. This model calibration was performed by a trial and error process of adjusting aquifer hydraulic conductivity, specific yield and river conductance to achieve a reasonable match between simulated and measured aquifer water levels and river gains and losses. For further details on model calibration, the reader is referred to IDWR (1997) and Johnson and others (1999). The following sections describe the water budget for the calibration period, the generation of initial conditions, and the estimation of recharge and discharge for the same period (April 1, 1980 through March 31, 1981).

Water Budget

Table 2 shows the water budget for the April 1, 1980 through March 31, 1981 period. Aquifer recharge and discharge during this period provided input for model calibration and is the base from which data sets for different time periods or development scenarios are developed.

The water budget for the model domain illustrates the relative magnitude of the major recharge and discharge components. It also provides an indication of the legitimacy of the conceptual model, based on how well independently derived terms balance. River gains and losses are based primarily on streamflow and diversion measurements. Changes in aquifer storage are based on estimates of specific yield and measured changes in water level. The net recharge component is estimated by the RECHARGE Program from data characterizing the irrigation systems, streams, and climate. The discrepancy is the difference between net recharge and discharge. Ideally, the discrepancy should be zero; however, the estimation of individual components of the water budget all contain some degree of error and the collective error is reflected by the discrepancy.

Initial Conditions

Initial estimates of the distribution of aquifer head are required for the transient model calibration period. Starting heads for the SRPAM1.1 model were derived from two sources. For the portion of the model that was converted from the original IDWR/UI Ground Water Flow Model, starting heads were taken from the original model starting heads. These initial heads were derived using RASA water level measurements from

Table 2. Conceptual Water Budget (1980-81 Calibration Year).

Component	Estimated Magnitude (AF/year)[1]
Net Recharge	**6,640,000**
Hydraulically Connected River Gains and Losses	
Above Lewisville[2]	-191,000
At Blackfoot to Neeley[2]	-1,706,000
Neeley to Minidoka[2]	-130,000
Milner to King Hill (North Side)[2]	-4,362,000
Total River Gains	**-6,389,000**
Change in Aquifer Storage[2]	**100,000**
Discrepancy	**351,000**

[1]positive value indicates recharge, negative value indicates aquifer discharge
[2]from Garabedian (1992)

early April, 1980 which were then interpolated to model cell centers. The specific set of water level measurements which were used to derive starting heads for the IDWR/UI Ground Water Flow Model is no longer available.

For the expanded portion of the model in the Henrys/South Forks area, 1980 RASA water-level measurements were contoured, the contours were adjusted to fit with contours published for that area by Wytzes (1978) and the contour interval was extrapolated to the RASA contours to the north which were published in Garabedian (1992). Contours representing the starting head conditions of April 1980 are available in Johnson and others (1999). Contouring of the measured starting heads introduces some error in the early stress periods of the model. However, a similar degree of error would

be introduced by any other method of generation of starting heads. The reader is referred to Johnson and others (1999) for more details on generation of starting heads in the expanded model region.

Calculation of Recharge and Discharge for SRPAM1.1

Aquifer recharge and discharge for the April 1980 through March 1981 period were estimated using the RECHARGE Program (Johnson and Brockway, 1983) for mechanisms that are independent of aquifer head. The program calculates the net recharge resulting from irrigation diversions and pumping; evapotranspiration from irrigated and non-irrigated land; canal, river, and stream seepage that are not dependent on aquifer head; and underflow from tributary valleys. The program computes the net recharge to every cell within the model domain based on inputs provided for each of the twenty-four 15.2-day stress periods. Boundary underflow, although computed as part of the RECHARGE Program, was discussed in the previous section on model boundaries. The other components of recharge and discharge estimation are discussed in the following sections.

Surface Water Diversions and Irrigation

Diversion and application of surface water for irrigation is one of the dominant contributors to recharge of the Snake River Plain aquifer. For the 1980 model calibration year (April 1, 1980 through March 31, 1981), the estimated surface water diversions totaled 9.5 million AF. Only irrigation companies with service area within the active model domain are included in this total. This water was distributed to about 1.6 million acres of surface water irrigated land on the eastern Snake River Plain. A cell by cell map of surface water irrigated areas is shown in Figure 13. A small fraction of these total

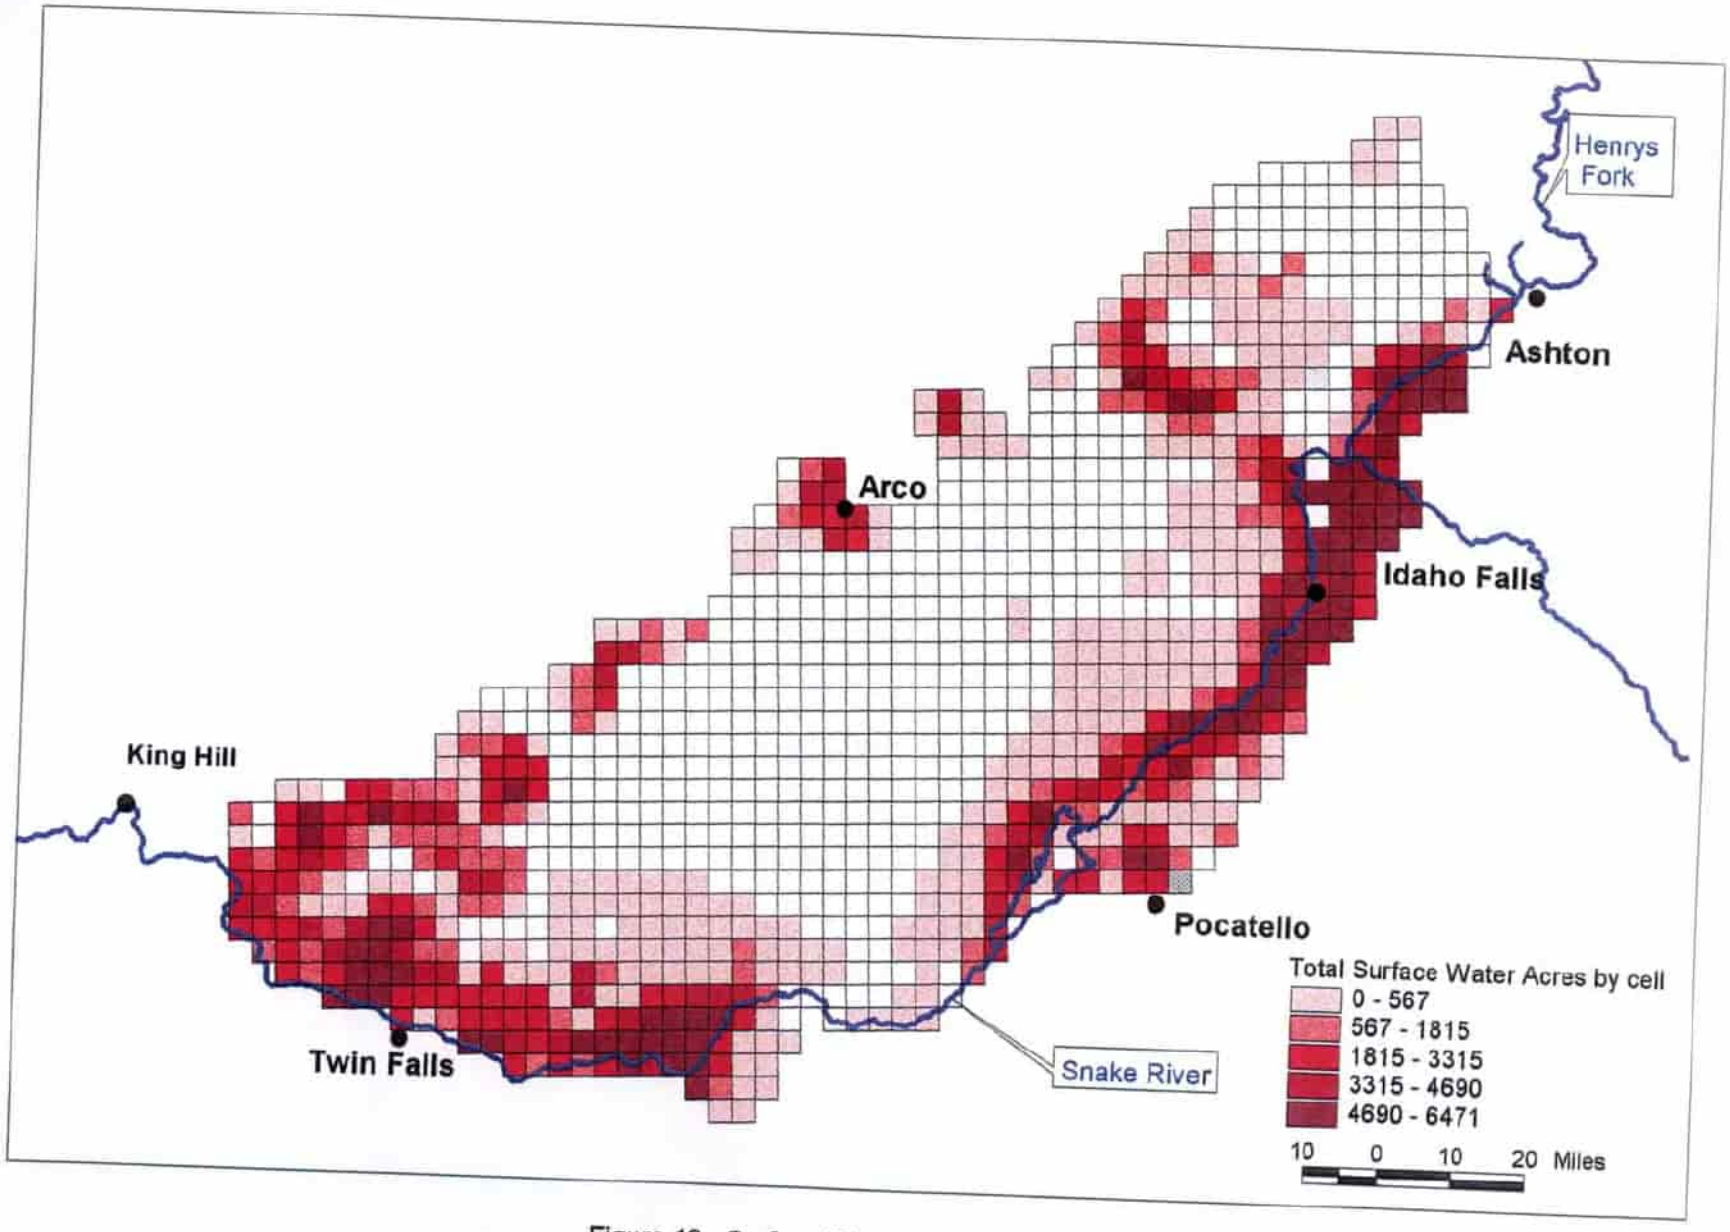

Figure 13. Surface Water Irrigated Acres.

EXHIBIT "505"
Page No. 44 of 101

002072

diversions actually represent ground water pumping, so a small number of ground water irrigated acres is included for some of the irrigation units. Cell dimensions are 5 km square, with each cell containing a total of about 6,150 acres. It is apparent from Figure 13 that most of the surface water irrigated areas lie in close proximity to the Snake River.

Irrigation applications were determined as the difference between irrigation diversions and return flows, divided by the number of irrigated acres. Computations of irrigation application were performed for each 15.2-day stress period and for each of 69 irrigation units. Irrigation units may contain multiple canal companies and include canal companies that pump ground water such as those near Mud Lake (Table 3). Irrigation diversions for each 15.2-day stress period and each irrigation unit were determined from IDWR records. Return flows were estimated from records when available. Irrigated area information was developed from Landsat MSS data, as described in Anderson (1983). Canal and lateral seepage is included in the irrigation application calculated by this method. Consequently, canal seepage is distributed in proportion to the irrigated area present in each model cell. The net diversion (minus surface return flow), irrigated area, and application rate (including canal seepage losses) for each irrigation unit are presented in Table 4. Irrigation companies with unknown rates of diversion were grouped into Irrigation Unit #70 (Table 3). An average rate of application was assumed for lands associated with this unit.

The temporal variation of irrigation applications, including canal seepage and ground water pumping irrigation units near Mud Lake, is shown in Figure 14. It is apparent from the figure that most of the recharge to the system originates from irrigation applications and canal seepage. The maximum irrigation applications in the calibration year occurred in mid-July.

Ground Water Pumping

Ground water pumping was the dominant form of non-head dependent aquifer discharge during the 1980-1981 calibration year. The ground water pumping estimate generated by the RECHARGE Program (and ultimately input to the model) is equal to crop consumptive use minus precipitation on lands identified as ground water irrigated. It is assumed that all pumping in excess of crop demands returns to the aquifer. In most cases this is a reasonable assumption. It is also assumed, except in specially treated areas near Mud Lake, that ground water pumping occurs in the same cell in which the irrigated lands are present. Ground water irrigated areas (Figure 15) were determined from Landsat MSS data, similar to surface water irrigated acres. The calculation of crop consumptive use is described in the next section.

Consumptive Use and Evapotranspiration

Applied irrigation water is either consumed by the crop (ET) or results in aquifer recharge. Therefore, aquifer recharge from surface water irrigation is calculated as the difference between crop consumptive use and the sum of precipitation and irrigation applications. For ground water irrigated areas the difference between crop consumptive use and precipitation represents the net ground water use.

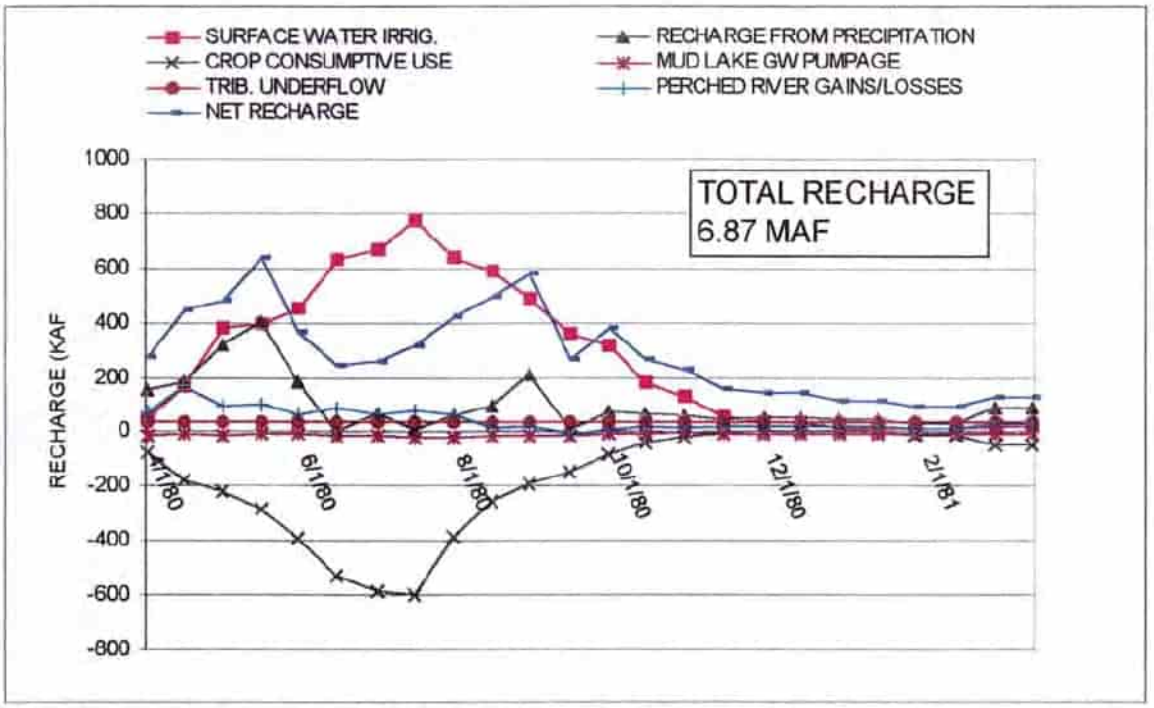

Figure 14. Time Distribution of Recharge for the 1980-1981 Calibration Data Set.

Crop consumptive use is estimated from measured climate data and crop distributions. The eastern Snake River Plain was divided into 12 climatic regions (Figure 16) for the original UI/IDWR Ground Water Flow Model; region 3 is located outside the ground water model area. These climatic regions extended far enough to cover the extended model boundaries, so no changes were made in assignment of climatic regions during model expansion. Weather conditions and crop distributions are determined for each region and control the evapotranspiration calculated for each region. Climate data are taken from nearby weather stations and crop distribution information was obtained from records of the USDA Agricultural Conservation and Stabilization Service. The annual crop consumptive use for the crop distribution of each region is color coded into Figure 16.

Crop consumptive use during the 1980 calibration year varies greatly with time of year. Figure 14 shows that crop consumptive use reaches a maximum of nearly 600,000 AF per 15.2-day stress period in mid-July. This corresponds well with the timing of the maximum irrigation diversions. The crop consumptive use is very significant in the overall water budget and is the principle negative component shown in Figure 14, indicating water leaving the system. The shape of the crop consumptive use graph, combined with the irrigation application largely controls the shape of the graph of net recharge in Figure 14.

Evapotranspiration from non-irrigated lands partially controls recharge from precipitation on these lands. Crop consumptive use from non-irrigated agricultural land was not evaluated because the total area of non-irrigated agricultural land is minimal relative to irrigated land. However, evaporation and transpiration on non-agricultural land controls the amount of recharge that results from precipitation on these lands. Recharge estimates for non-irrigated lands were based on the amount of non-irrigated land within a cell, the soil cover and vegetation and weather characteristics. Figure 17 shows the estimated recharge on non-irrigated lands within the modeled area. Seven model cells in Figure 17 show a negative value of recharge on non-irrigated land. These values are small and are the result of errors resulting from data processing. Recharge from precipitation is greatest in areas of high precipitation and little soil cover.

The temporal variation of recharge from precipitation on irrigated and non-irrigated lands was bi-modal during the 1980 calibration year (Figure 14). The maximum rate of recharge occurred in spring as expected. A second, smaller peak occurred in late summer of the calibration year and probably is atypical.

River, Stream, and Canal Losses

Some streams emerging from the mountains surrounding the plain lose water to the aquifer through seepage. In most locations the aquifer is sufficiently far below land surface that the stream losses are unaffected by aquifer water level. In these situations, stream recharge is included in the calculations of the RECHARGE Program as a specified flux to the aquifer.

The location of specified flux river nodes representing recharge from stream seepage is shown in Figure 18. Each cell with specified seepage shown in Figure 18 is assigned to a stream reach number. Table 5 lists the rate of flux for each stream reach number shown in Figure 18. Flux is uniformly divided among the cells within a reach. The temporal variation in total stream seepage shows a maximum in mid-April, as can be seen in Figure 14. The magnitude of this component is small relative to other elements contributing to the net recharge.

Tributary Valley Underflow

Figure 12 shows the location of model cells with fixed tributary underflow entering the model area. Each model cell with tributary underflow is assigned to an underflow zone. The annual rate of underflow and the tributary basin assigned to each underflow zone are listed in Table 6. Underflow is uniformly divided among cells composing an underflow zone and is time-constant as evident from Figure 14.

Table 5. Fixed Stream Seepage Values.

Number	Description	Specified Flux(AF/Yr)
1	Snake River Below Milner	-23000
2	Snake River Minidoka to Milner	281400
3	Snake River Neeley to Minidoka	0[1]
4	Snake River Near Blackfoot to Neeley	0[1]
5	Snake River Shelley to Abv. Blackfoot	111350

Net Recharge

The net recharge computed by the RECHARGE Program involves all of the above components. It does not include river gains and losses that are affected by aquifer water level (head-dependent). These gains and losses are simulated by the model. The computed net recharge to the model domain varies temporally and areally. The temporal variation (Figure 14) shows net recharge is predominantly related to surface water application (diversions minus return flows), evapotranspiration, and precipitation patterns. Tributary valley underflow represents a relatively small and time constant contribution to recharge. Seepage from perched streams (non-head dependent) is also relatively small but varies seasonally. The line representing off-site well pumpage (Figure 14) refers to cases where several miles separate the point of ground water pumping and application of the same water, for example, in the Mud Lake area. In the 1980 calibration year, maximum recharge occurred in late May and early September, when diversions were large but evapotranspiration was less than the maximum. In this particular year, recharge in early September was supplemented by significant precipitation.

The areal distribution of recharge shows that recharge is greatest in surface water irrigated areas where recharge rates are positive (Figure 19). Large recharge rates also are associated with a relatively few cells representing underflow from tributary valleys. Discharge in excess of recharge associated with net ground-water withdrawals are

modal nature of the histogram differs from an expected distribution of specific yields which would occur naturally in an unconfined system. The high number of model cells with specific yields in the .3 to .35 range may be a relic of the automatic calibration process and may not accurately reflect the physical system.

A table which compares river cell properties for SRPAM1.1 and the USGS Snake River Plain Model is in the Appendix. This table contains the calibrated riverbed conductance values for both models.

LIMITATIONS OF SRPAM1.1

All model applications are imperfect representations of the real world and therefore they always can be improved. The improvement process should involve prioritizing the needs associated with the limitations of any application. Further work should then address the limitations of highest priority. This section outlines the major limitations of SRPAM1.1.
