Preliminary Plan for ESPA CAMP
Modeling Scenario

ESPA CAMP Meeting
November 15, 2007
Burley, Idaho

Brian Patton
Idaho Department of Water Resources
Assignment from the CAMP Subcommittee was to evaluate the reach gain and water level changes from a 600KAF – 900KAF change in the ESPA water budget.

Because the effects differ depending on what actions are used, and where they occur, we had to make a number of assumptions regarding actions and locations.
The following is a preliminary plan meant to begin the discussion and analysis of options to change the ESPA water budget. This plan outlines one combination of management options that achieves a change of 900KAF. There may be other alternatives not shown, or they may be applied in different combinations than shown here.
A&B Conversion

- Convert A&B Irrigation District to a surface water supply. This would remove 60,000 acres from ground water pumping.
- Water would be supplied from the High-Lift exchange and new storage.
- Would require new delivery infrastructure.
Managed Recharge

- Utilize the Water Board’s recharge water right, assuming a resolution to the Milner Hydro Permit or a negotiated settlement with permit holders.

- Split available flow between upstream and downstream of American Falls based on water availability and water right constraints.
Managed Recharge Below American Falls

- Utilize full diversionary capacity of Northside and Milner-Gooding canals after March 1st, in excess of irrigation deliveries and when the IWRB natural flow water right is in priority.

- Assume all water diverted for recharge can be recharged. This will require significant new construction.
Managed Recharge Above American Falls

● Utilize full diversionary capacity of Aberdeen-Springfield, Egin Bench and other canals after March 15th, in excess of irrigation deliveries and when the IWRB natural flow water right is in priority.

● Assume all water diverted for recharge can be recharged. This will require significant new construction.
CREP

- Assume modifications and incentives to CREP to achieve the full 100,000 acre enrollment limit.
Soft Conversions

- Opportunistically pursue soft conversion projects where excess water exists, canal capacity to mixes-source lands exists, and timing allows.
Remaining Measures

- Assume any remaining shortfall in water budget change will be accomplished through reduced pumping through voluntary measures such as buy-outs, dry-year leases, or other similar measures.
Assume the construction of 50 KAF of new storage through the Minidoka enlargement, or through off-stream sites below American Falls. This water would be needed to achieve the A&B conversion.

Begin evaluating 300 KAF of new storage above American Falls, but because this would be several decades to completion, it is not included in this modeling exercise.
Salmon Flow Exchange

- Assume all available salmon flow augmentation water released from Upper Snake storage is exchanged for use on the Snake River Plain. This is needed for both the A&B conversion and for soft conversions.

- The salmon flow would be replaced with water from below-Milner sources, such as high-lift buyouts or new storage in southwest Idaho.
